OSHA has concluded from the evidence in the record (March 17, 1978 final rule on DBCP) that DBCP presents a hazard of cancer and sterility to exposed workers. The results of welldesigned animal studies indicate DBCP to be a potent carcinogen in two sexes of two mammalian species at two dose levels. Furthermore, DBCP has been found to cause positive results in microbial assays designed to detect chemicals capable of mutagenesis. This evidence, which was not seriously challenged by any of the participants in the Agency's 1978 proceeding, leads to the conclusion that DBCP must be regulated as a human carcinogen.

Animal studies have also demonstrated that oral doses of DBCP induce degeneration of testicular tissue, accompanied by a reduction of sperm count and abnormal sperm cell development. These testicular effects were confirmed in humans with the discovery of sterility and infertility in a large number of male employees exposed to low levels of DBCP in the manufacture and formulation of pesticides. This evidence was also uncontroverted by hearing participants in the earlier 6(b) rulemaking.

Accordingly, OSHA has concluded that the proven carcinogenic and sterilant potential of DBCP warrants limiting exposure to the lowest level feasible. OSHA has therefore established an eight-hour time-weighted average permissible exposure limit of 1 part per billion (ppb) for this substance. OSHA has concluded, based on evidence presented in the record, that this limit represents the lowest exposure level achievable using present technology.

Based on this evidence, OSHA concluded in 1978 that exposure to DBCP causes cancer and sterility in humans and animals. OSHA therefore

believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed limit of 1 ppb (0.001 ppm) as an 8-hour TWA, and a skin notation, is necessary to significantly reduce these risks of material health impairment among these workers. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

DIMETHYL SULFATE
CAS: 77-78-1; Chemical Formula:
(CH₃)₂SO₄
H.S. No. 1142

OSHA's limit for dimethyl sulfate in the construction and maritime industries is 1 ppm as an 8-hour TWA, with a skin notation. The Agency has no PEL for this substance in agriculture. The ACGIH considers dimethyl sulfate a suspected human carcinogen and has given it an A2 classification. The ACGIH's TLV®-TWA for this substance is 0.1 ppm, with a skin notation. There is no REL for dimethyl sulfate; however, NIOSH (Ex. 8-47, Table N6A) concurred with the selection of this limit. OSHA is proposing a PEL of 0.1 ppm, with a skin notation, as an 8-hour TWA for dimethyl sulfate in the construction, agriculture, and maritime industries. This is the limit recently established in general industry.

Dimethyl sulfate is an oily, colorless liquid with a faint onion-like odor. It is commonly used as a methylating agent in the manufacture of many organic chemicals (ACGIH 1986, p. 212).

In addition to cancer, exposure to dimethyl sulfate causes severe irritation and burns of the eyes, skin, mucous membranes, and lungs in animals and humans. The oral LD50 in rats is 205 mg/ kg, and the LCso in the same species is 45 mg/m3 for 4 hours RTECS 1990) Mice, rats, and guinea pigs exposed to a 75 ppm concentration of dimethyl sulfate for 17- to 26-minute periods developed pulmonary edema, emphysema, and peribronchitis; autopsy revealed necrosis and fatty infiltration of the liver in these animals (HSDB 1985). Instilled into rabbit eyes and rinsed out almost immediately, dimethyl sulfate nonetheless caused severe irritation; skin contact with the liquid is also severely damaging (RTECS 1990).

Several human fatalities have resulted from industrial accidents involving this substance (Fairhall 1957). Death is caused in these cases by circulatory failure and follows a lengthy interval in which the victim experiences difficult breathing, vomiting, diarrhea, dysuria, and edema of the larynx (Bartalini et al. 1957, Nebelung 1957, Roche et al. 1962).

In near-lethal cases, residual effects may persist for years after the incident.

If dimethyl sulfate is splashed into the eye, it causes both acid-type burns and severe, delayed-onset denaturation and necrosis (Grant 1986, p. 350). Contact of the liquid with the skin similarly causes severe necrosis and blistering (HSDB 1985). Dimethyl sulfate is such a severely corrosive substance that it was used as a poison gas during World War

The following paragraphs describe dimethyl sulfate's carcinogenicity in animals. The carcinogenic activity of dimethyl sulfate was investigated in male rats chronically exposed to subcutaneous injections of 8 or 16 mg/kg per week (Druckrey, Preussman, Nashed, and Ivanovic 1966/Ex. 1-245). Local sarcomas with metastases to the lung and regional lymph nodes were observed at both dose levels. A single subcutaneous injection of dimethyl sulfate (50 mg/kg) also produced local sarcomas with metastases to the lung (Druckrey, Kruse, Preussman et al. 1970/ Ex. 1-246). However, tumors did not develop following chronic weekly intravenous injections of dimethyl sulfate (2 or 4 mg/kg) (Druckrey, Kruse, Preussman et al. 1970/Ex. 1-246). Control data were not reported for either of these studies.

The carcinogenic potential of dimethyl sulfate exposure by inhalation was also evaluated in a bioassay involving male rats (Druckrey, Kruse, Preussman et al. 1970/Ex. 1–246). Animals were exposed to approximately 3 or 10 ppm dimethyl sulfate for 1 hour per day, five times weekly, for 130 days. Malignant tumors developed in 15 percent (3/20) of the rats exposed at 3 ppm and in 18 percent (5/27) of the rats exposed at 10 ppm.

Pregnant rats were exposed to a single intravenous injection of dimethyl sulfate [20 mg/kg body weight] on day 15 of gestation, and the incidence of malignant tumors in the offspring was investigated in litters produced for one year following this exposure; tumors were reported in 7/59 of the offspring. The results of this study are difficult to interpret because several rats in the study died (number of deaths not specified) from the acute toxic effects of dimethyl sulfate, and the incidence of tumors in the control group was not reported.

There is little information available regarding the carcinogenicity of dimethyl sulfate in humans. A case study of workers exposed to dimethyl sulfate reported that three of these workers developed bronchial cancer (Druckrey, Preussman, Nashed, and Ivanovic 1966/Ex. 1–245). However, an epidemiological study by the E.I. du Pont

de Nemours Company (1975, as cited in ACGIH 1986/Ex. 1-3, p. 213) demonstrated no increase in the incidence of respiratory cancer among workers exposed to dimethyl sulfate.

In the prior air contaminants rulemaking, OSHA considered the possibility of performing a quantitative risk assessment for dimethyl sulfate and concluded that the studies described above did not have sufficient doseresponse data to provide an adequate basis for such a risk assessment (Ex. 85). Dimethyl sulfate induces malignant tumors in animals both by inhalation and ingestion, and there is thus sufficient evidence in animals to predict that workers exposed to dimethyl sulfate are at significant risk of developing cancer; exposures at levels only three times the current PEL (1 ppm) resulted in a significant number of tumors. OSHA also notes that the International Agency for Research on Cancer concluded, on the basis of the evidence described above, that dimethyl sulfate should be considered a carcinogen in animals (IARC 1987, p. 200). Accordingly, OSHA preliminarily concludes that the proposed 0.1-ppm 8hour TWA PEL, with a skin notation, will substantially reduce the significant risk of cancer mortality associated with exposure to dimethyl sulfate in the construction, agriculture, and maritime industries. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

ETHYLENE OXIDE

CAS: 75-21-8; Chemical Formula: C₂H₄O H.S. No. 2083

In general industry, construction, and maritime, OSHA's permissible exposure limit for ethylene oxide (EtO) is 1 ppm as an 8-hour TWA and 5 ppm as a 15minute excursion limit. There is no limit in agriculture. The ACGIH designates EtO as an A2 carcinogen and assigns it an 8-hour TLV*-TWA of 1 ppm. NIOSH considers this substance a potential occupational carcinogen and has a REL of less than 0.1 ppm as an 8-hour TWA and 5 ppm as a 10-minute ceiling. OSHA is proposing an 8-hour TWA of 1 ppm and a 15-minute excursion limit of 5 ppm for EtO in agriculture. Promulgation of these limits will make the PELs for ethylene oxide consistent across all OSHA-regulated sectors.

Ethylene oxide (EtO), also known as 1,2-epoxyethane, oxirane, and dimethylene oxide, is a colorless gas with a characteristic ether-like odor. Although several processes exist for the production of EtO, all United States producers currently manufacture EtO

through the catalytic oxidation of ethylene in the presence of a silver catalyst. EtO is completely miscible with water, alcohol, acetone, benzene, ether, carbon tetrachloride and most organic solvents. It is also highly reactive. In order to reduce explosion hazards when EtO is used as a fumigant or sterilant, it is often used in gaseous mixtures (such as 10% EtO and 90% CO2 or 12% EtO and 88% halocarbon). Since its first domestic production in 1925, EtO has become a major industrial chemical and is presently one of the 25 highest production volume chemicals in the United States. During the period from 1967 to 1978, for example, the average rate of growth in the EtO industry was 6.7 percent. In 1990, over 5.2 billion pounds of EtO were produced domestically.

The primary use of EtO is as an intermediate in the manufacture of other products. Over 99% of total EtO production is used in the manufacture of other products, and almost 90% is consumed by the EtO manufacturers themselves. On a volume basis, the largest use of EtO is as an intermediate in the production of ethylene glycol, a major component of automotive and other anti-freeze products. Approximately 70 percent of all domestically produced EtO goes into the manufacture of ethylene glycol.

EtO is also widely employed in the production of non-ionic surface-active agents which are used in household detergents and as industrial sufactants. Other products manufactured from EtO include: (1) Ethanolamine, used in sweetening natural gas and in the production of specialty chemicals, detergents and cosmetics; (2) glycol ethers, utilized as a jet fuel additive and in the formulation of coatings, cleaners, automotive brake fluids and inks; (3) diethylene and triethylene glycol, used in drying natural gas and in the manufacture of polyester resins, emulsifiers, lubricants and plasticizer; (4) tetraethylene glycol, utilized to extract aromatic hydrocarbons from nonaromatic hydrocarbons; (5) polyethylene glycol, from which cosmetics, plasticizer, lubricants and dispersants are produced; (6) polyethylene glycol, used for water soluble packaging and for warp sizing, and (7) crown ethers, used for extraction of liquids.

A small fraction of EtO production (less than 0.5 percent) is consumed by sterilant or fumigant users. EtO is utilized as a sterilizing agent by various facets of the health care industry for the sterilization of delicate instruments and heat- or moisture-sensitive devices, and

is employed as a fumigant for a number of miscellaneous items, such as spices, black walnut meats, books, furniture, textiles, empty bin equipment, empty cargo holds, cosmetics, and dairy packaging. When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

OSHA has found that EtO can cause several serious adverse health effects. Studies in experimental animals supported by epidemiological studies of working populations indicate that EtO is a potential occupational carcinogen. The evidence suggests that EtO may cause cancers of the blood (leukemia), as well as other organs in humans. In addition, EtO exposure cause mutations, increases the rate of chromosomal aberration and sister chromatid exchange, and causes other undesirable changes in the DNA of mammalian cells. These effects support OSHA's conclusion regarding the carcinogenicity of EtO. EtO exposure has also been associated with an increased risk of spontaneous abortion among pregnant women and is capable of causing other adverse reproductive effects in both men and women. Exposure to high concentrations of EtO causes central nervous system depression and other neurological effects that are thought to be reversible with cessation of exposure. In addition, exposure to EtO gas causes sensitization and irritation of human tissues, including the eyes and respiratory tract.

Three epidemiological studies indicate an association between worker exposure to EtO and a significant increase in the risk of death from cancer. Hogstedt et al. (Ex. 208) found an increased risk of death from leukemia among employees exposed to EtO when this substance was used as a sterilant. In a second study, these investigators confirmed an increased leukemia risk and also observed a significant excess of stomach cancer deaths and total cancer deaths among production workers (Ex. 2-22). Morgan et al. (Ex. 6-5) found an increased risk of mortality from Hodgkin's disease and pancreatic cancer among EtO

production workers.

Studies in experimental animals have provided definitive evidence that EtO is carcinogenic in multiple species and by several routes of administration. Leukemia, brain cancer, and mesothelioma have been induced in animals exposed to EtO by inhalation. Cancers of the forestomach have been induced as a result of EtO administration by oral gavage. Injection site sarcomas and skin cancers have been observed in animals exposed to EtO by injection.

Additional evidence regarding the adverse health effects of EtO on both humans and animals was presented in the preamble to OSHA's Final Rule on Occupational Exposure to Ethylene Oxide (FR June 22, 1984).

In the absence of a limit for EtO in agriculture, OSHA preliminarily concludes that exposed workers are at significant risk of developing leukemia and other cancers, as well as neurologic effects. OSHA believes that promulgation of the 1 ppm 8-hour TWA PEL and the 5 ppm 15-minute excursion limit is necessary to reduce this risk. Therefore, OSHA is proposing to apply these limits to agriculture. In addition, promulgation of these limits will make OSHA's PELs for EtO consistent across all regulated sectors.

FORMALDEHYDE

CAS: 30-00-0; Chemical Formula: CH2O H.S. No. 2085

In general industry, construction, and maritime, OSHA's permissible exposure limits for formaldehyde are 1 ppm as an 8-hour TWA and 2 ppm as a 15-minute STEL. There is no limit in agriculture. The ACGIH designates this substance an A2 carcinogen and assigns it an 8hour TLV®-TWA of 1 ppm and a 15minute STEL of 2 ppm. NIOSH considers formaldehyde a potential occupational carcinogen and has a REL for formaldehyde of 0.016 ppm as an 8-hour TWA and 0.1ppm as a 15-minute ceiling. OSHA is proposing a PEL of 1 ppm as an 8-hour TWA and 2 ppm as a 15-minute STEL for formaldehyde in agriculture. Promulgation of these limits will make the PELs for formaldehyde consistent across all OSHA-regulated sectors.

The chemical called "formaldehyde" is a colorless, pungent gas at room temperature that has an approximate odor threshold of about 1 ppm. The simplest member of the aldehyde class of chemicals, formaldehyde has a molecular weight of 30. Although the term "formaldehyde" is also used to describe various mixtures of formaldehyde, water, and alcohol, the term "formalin" more precisely describes aqueous solutions, particularly those containing 37 to 50 percent formaldehyde and 6 to 15 percent alcohol stabilizer. Most formaldehyde enters commerce as formalin. Alcoholic solutions of formaldehyde are available for processes that require low water content (Ex. 753-53). Para-formaldehyde, a solid, also serves as a source of formaldehyde

gas. Formaldehyde gas, per se, is not available commercially.

Formaldehyde is a major industrial chemical, ranked 24th in production volume in the United States (Ex. 138–F). In 1985, 5.7 billion pounds of 37 percent formaldehyde (by weight) was produced. Formaldehyde is produced in 49 plants in the U.S. by one of two processes: the mixed oxide catalyst process or the silver oxide catalyst process. Both processes use methanol as the product precursor and they differ in catalyst type, operating temperature, and methanol/air ratios.

About two-thirds of annual production is used on-site or at nearby locations. For example, a major use of formaldehyde is in the preparation of adhesive resins for use in the wood products industry. These resinproducing facilities tend to be located in lumber producing areas of the South and

West.

Formaldehyde has a high degree of chemical reactivity because of its unique chemical structure, i.e., a carbonyl group attached to hydrogen atoms. As a result it undergoes a wide variety of chemical reactions in three distinct classes: oxidation-reduction reactions, addition or condensation reactions, and self-

polymerization.

Formaldehyde has four basic uses: as an intermediate in the production of resins; as an intermediate in the production of industrial chemicals; as a bactericide or fungicide; and as a component in the formulation of end-use consumer items. The manufacture of three types of resins: Ureaformaldehyde, phenol-formaldehyde and melamine formaldehyde, accounts for about 59 percent of total consumption. An additional seven percent is consumed in the production of thermoplastic acetal resins. About onethird is used in the synthesis of highvolume chemical derivatives, including pentaerythritol,

hexamethylenetetramine, and butane. Two percent is used in textile treating and amounts of formaldehyde are present as preservatives or bactericides in consumer and industrial products, such as cosmetics, shampoos, and glues. When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Workers have developed various health effects from inhalation of airborne formaldehyde and from dermal contact with formaldehyde solutions or products containing formaldehyde. At airborne concentrations as low as 0.1 ppm, formaldehyde causes irritation of the eyes, nose, and throat. As airborne

concentrations increase, the severity of the irritation increases, and irritation spreads from the nasal passages and throat into the lower respiratory system. Very severe conditions, e.g., exposures above 50 ppm, have caused severe lacrimation (tearing of the eyes) and pulmonary reactions, including pneumonia, bronchial inflammation, and pulmonary edema. Massive inhalation of formaldehyde has caused accidental death in humans. A concentration of 100 ppm is "immediately dangerous to life and health" (IDLH) and is believed to be a potentially fatal level if exposure continues for 30 minutes or more.

Long-term inhalation of formaldehyde gas is associated with nasal cancer in experimental animals. Some studies in humans exposed to formaldehyde have demonstrated increased nasal and nasophrygeal cancer. Thus, formaldehyde should be regarded as an

occupational carcinogen.

Skin irritation is a well-known consequence of dermal contact with formaldehyde. Formaldehyde reacts with skin, resulting in a response not unlike the effects seen in the tanning of leather. Employees such as pathologists or undertakers, who handle embalming fluids or other concentrated solutions of formalin, frequently show evidence of skin disease. Dermal contact with formaldehyde-bearing resins has also caused skin disorders (see the NIOSH Health Hazard Evaluations, in Exs.78 and 85, for example).

Dermal sensitization to formaldehyde is a well-known phenomenon. Among atopic individuals seeking assistance at allergy clinics, formaldehyde is among the top 10 sensitizers found in patch testing results. A person sensitized to formaldehyde would have serious difficulties working in industries, such as garment manufacturing or textile finishing, where there is repeated dermal contact with sensitizing materials. Sensitization is not readily reversed, which means that a worker who is sensitized may be unable to continue his or her line of work.

OSHA estimated in the 6(b) rulemaking for formaldehyde that the maximum likelihood estimate (MLE) cancer risk for employees exposed for a lifetime to formaldehyde is 0.6 deaths per 1,000 workers at 1 ppm. This risk estimate and estimates of this risk at other levels were based on the rat study conducted by the CIIT. Information regarding the risk assessment and the health effects of formaldehyde is extensive, and was discussed at length in the preamble to OSHA's Final Rule on Occupational Exposure to Formaldehyde (F.R. publication, December 4, 1987). References cited in

this discussion can be found in that preamble.

Based on this evidence in humans and animals, OSHA concluded in that rule that exposure to formaldehyde causes cancer sensitization, respiratory tract irritation, and other systemic effects in humans and animals. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed limits of 1 ppm as an 8hour TWA and 2 ppm as a 15-minute STEL are necessary to significantly reduce these risks of material health impairment among these workers. Promulgation of these limits will also make the PELs for formaldehyde consistent across all OSHA-regulated sectors.

2-NITROPROPANE
CAS: 79-46-9; Chemical Formula:
CH₃CH(NO₂)CH₃
H.S. No. 1291

OSHA's limit for 2-nitropropane (2-NP) in the construction and maritime industries is 25 ppm as an 8-hour TWA. The Agency has no PEL for this substance in agriculture. The ACGIH classifies 2-nitropropane as a suspected human carcinogen (A2) and has assigned it a TLV*-TWA of 10 ppm. NIOSH considers 2-nitropropane a potential human carcinogen and recommends that exposure be reduced to the lowest feasible limit. OSHA is proposing a 10 ppm 8-hour TWA PEL for 2-nitropropane in the construction, agriculture, and maritime industries. This is the limit recently established for this substance in general industry.

2-Nitropropane is a colorless liquid. It is used as a chemical intermediate, a solvent, and a component in paint, ink, and varnishes (Fiala, Czenniak, Castonguay et al. 1987/Ex. 1–248).

In addition to cancer, exposure to 2-NP causes pulmonary irritation and, in animals, liver damage. The oral LD50 in rats is 720 mg/kg, and the LCoo in the same species is 400 ppm for 4 hours (RTECS 1990). Acutely poisoned animals developed cyanosis, convulsed, and became comatose before death (Clayton and Clayton 1982, p. 4159). Pulmonary edema and hemorrhage and damage to the liver were seen in these animals at autopsy (Clayton and Clayton 1982, p. 4159). Cats, rabbits, guinea pigs, and monkeys were exposed to 83 or 328 ppm for 7 hours/day; cats succumbed after a few days of such exposure, but the other animals survived 130 (guinea pigs, rats, and rabbits) or 100 (monkeys) of these exposures (Clayton and Clayton 1982, p.

Acute effects have been reported in workers exposed either to 2–NP alone or in combination with other substances. A concentration of 20 to 45 ppm xylene and 2–NP caused gastrointestinal symptoms, headache, and anorexia in exposed workers (Skinner 1947). Irritation of the respiratory tract was reported by workers exposed to 2–NP at concentrations ranging from 30 to 300 ppm (AIHA 1978). The following paragraphs describe the carcinogenicity of 2-nitropropane in experimental animals.

The mechanisms of carcinogenicity of 2-NP are thought to involve the release of nitrite and the formation of a reactive azoxy intermediate that can react with cellular macromolecules (Williams and Weisburger 1986/Ex. 1-65). In mutagenicity tests, 2-NP increased the frequency of mutations in all strains of Salmonella typhimurium with and without metabolic activation. Positive mutagenicity results were reported in Salmonella typhimurium strains TA100. TA1535, and TA98 by Lofroth, Nilsson, and Anderson (1981) and by Speck, Meyer, Zeiger, and Rosenkranz (1982/ Ex. 1-290).

The available epidemiology data on the chronic health effects of occupational exposure to 2-NP do not contain sufficient dose-response data to use as a basis for quantitative risk estimation. An unpublished retrospective mortality study of 1,481 potentially exposed workers from a nitropropane production plant found no increase in liver cancer or liver disease mortality. However, lack of exposure data, the small number of workers with long exposures (greater than 15 years), and a short latency period make interpretation of the results of this study difficult (Miller and Temple 1979; Bolender 1983).

There are two studies that report high incidences of liver tumors in male rats exposed to 2-NP by gavage and inhalation. Fiala et al. (1987/Ex. 1-248) administered, by gavage, 1mmol/kg body weight (approximately 27 mg per treatment per 300-gram rat) of 2-NP in a 10-percent aqueous Emulphor EL-820 vehicle to male Sprague-Dawley rats three times weekly for 16 weeks. Dosing was discontinued after 16 weeks because of excessive mortality in the treated rats. Seventy-seven weeks from the first treatment, the surviving rats were sacrificed and subjected to necropsy. All (100 percent) of the treated rats examined had developed hepatocarcinomas (Fiala, Czenniak, Castonguay et al. 1987/Ex. 1-248).

The results of the Fiala et al. (1987/Ex. 1-248) study support the earlier positive results reported by Lewis, Ulrich, and

Busey (1979/Ex. 1–826). In the Lewis et al. (1979/Ex. 1–826) study, male Sprague-Dawley rats and male New Zealand White rabbits were exposed via inhalation to 27 ppm or 207 ppm of 2–NP for 7 hours/day, 5 days/week for 8 months. At the end of 6 months, all 10 rats in the high-dose group exhibited hepatocellular carcinomas and neoplastic nodules. No exposure-related lesions were seen in the rats exposed to 27 ppm, and no exposure-related lesions were observed in any of the rabbits.

One high-dose and two low-dose studies reported negative results for rats exposed to 2-NP vapors. Griffin, Benitz, Coulston, and Rosenblum (1978/Ex. 1-243) reported no hepatic carcinomas in male and female rats exposed to 200 ppm of 2-NP by inhalation using a protocol similar to that described by Lewis et al. (1979/Ex. 1-826). Although no hepatic carcinomas were observed, the following effects (generally occurring more extensively in males) were seen: Increased liver weights (both sexes); hepatic nodules; hepatocellular necrosis; and peripheral compression.

Two low-dose studies (Griffin, Coulston, and Stein 1980/Ex. 1–268; Griffin, Stein, and Coulston 1981/Ex. 1–279) also produced negative results. Male and female Sprague-Dawley rats were exposed by inhalation to 25 ppm of 2–NP for seven hours/day, five days/week for 22 months. No pathological changes associated with exposure to 2–NP were seen.

Although the results of both the Lewis et al. (1979/Ex. 1–826) and the Fiala et al. (1987/Ex. 1–248) studies show statistically significant increases in liver carcinomas, neither study provides sufficient dose-response information to use as a basis to quantify the excess cancer risk to humans exposed to 2–NP. Both studies were terminated before the natural lifetime expectancy of the controls, so it is not possible to determine a background incidence of cancer risk. No historical information is provided on tumor incidence for these animals.

2-Nitropropane produced a high incidence of liver tumors in male rats by two routes of administration: inhalation and ingestion. Its ability to cause mutations in Salmonella typhimurium further supports the premise that 2-NP is a potential human carcinogen. In the prior rulemaking, OSHA considered whether to perform a quantitative risk assessment on 2-NP and concluded that the studies described above do not contain sufficient dose-response data to use as the basis for quantitative risk estimation using standardized risk assessment models. However, two studies (Fiala, Czenniak, Castonguay et

al. 1987/Ex. 1–248; Lewis, Ulrich, and Busey 1979/Ex. 1–826) demonstrate that exposure to 2–NP, either by gavage or inhalation, produced hepatocarcinomas in rats. In addition, this substance produced positive results in two mutagenic assays (Lofroth, Nilsson, and Andersson 1981; Speck, Meyer, Zeiger, and Rosenkranz 1982/Ex. 1–290).

Based on this evidence, OSHA is proposing an 8-hour TWA PEL for 2-NP of 10 ppm in the construction, agriculture, and maritime industries. The Agency preliminarily concludes that a reduction in the PEL is necessary to protect exposed workers in these sectors from the significant risk of cancer potentially associated with exposure to 2-NP at the former PEL. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

PERCHLOROETHYLENE (TETRACHLOROETHYLENE) CAS: 127-18-4; Chemical Formula; CCl₂=CC₂ H.S. No. 1308

OSHA's permissible exposure limit for perchloroethylene (tetrachloroethylene) in the construction and maritime industries is 100 ppm as an 8-hour TWA. The Agency has no PEL in agriculture for this substance. The ACGIH TLV*s are 50 ppm as a TWA and 200 ppm as a STEL. NIOSH considers perchloroethylene a potential human carcinogen and recommends minimizing workplace exposure concentrations to the lowest levels feasible. After reviewing extensive comments in the rulemaking for general industry, OSHA concluded that perchloroethylene is a potential human carcinogen and established a 25 ppm PEL as the lowest level for which the Agency had evidence of feasibility. OSHA is proposing this PEL of 25 ppm as an 8-hour TWA for perchloroethylene in the construction, agriculture, and maritime industries. This is the limit recently established in general industry.

Perchloroethylene is a clear, colorless, nonflammable liquid with an ethereal odor. It is widely used as a solvent in the dry cleaning industry and in industrial degreasing operations.

The oral LD_{bo}s of perchloroethylene in rats and mice are 8850 and 8100 mg/kg, respectively. The narcotic effects associated with acute exposure to perchloroethylene are well documented. Four human subjects exposed to a 5000-ppm concentration for 6 minutes experienced vertigo, nausea, and mental confusion for 10 minutes. Mild central nervous system depression results from exposure to 2000 ppm for 5 minutes, and

exposure to 600 ppm for 10 minutes is associated with dizziness, numbness around the mouth, and incoordination. Exposure to 100 ppm for 7 hours has resulted in mild irritation of the nasal passages, eyes, and throat; headache; facial flushing; and slurred speech (Proctor, Hughes, and Fischman, 1988, pp. 399-400). The most comprehensive studies of the effects of prolonged exposure to perchloroethylene vapors on human volunteers were conducted by Stewart and colleagues (Stewart, Hake, LeBrun et al. 1974/Ex. 1-970; Stewart, Hake, Wu et al. 1977/Ex. 1-971); these investigators concluded that prolonged exposure to 200 ppm results in early signs of CNS depression, while no response was elicited in men or women exposed repeatedly to 100 ppm for seven hours/day, except that performance on the Flanagan coordination test was significantly decreased in some exposed subjects (Stewart, Hake, Wu et al. 1977/ Ex. 1-971, p. 28).

Chronic exposure to perchloroethylene has been associated with neurological abnormalities. including impaired memory, numbness of the extremities, peripheral neuropathy, and impaired vision. Twenty-one of 40 dry-cleaning workers exposed to perchloroethylene concentrations up to 300 ppm showed abnormalities of the autonomic nervous system. Twenty dry-cleaning workers exposed for an average of 7.5 years to concentrations ranging from 1 to 40 ppm had altered electrodiagnostic and neural rating scores (Proctor, Hughes, and Fischman, 1988, pp. 399-400). In addition to examining the evidence for the chemical's narcotic effects, OSHA reviewed a number of studies on the carcinogenicity of perchloroethylene. These investigations are summarized below.

In a 1977 gavage bioassay for carcinogenicity, perchloroethylene was shown to be a liver carcinogen in mice but not in rats (NCI 1977c, as cited in ACGIH 1986/Ex. 1-3, p. 464). In 1986, the NTP conducted an inhalation bioassay of perchloroethylene (NTP 1986b/Ex. 8-31, Appendix 4), in which groups of 50 male and 50 female F344/N rats and B6C3F1 mice were exposed to perchloroethylene for 6 hours/day, 5 days/week, for 2 years. The exposure concentrations were 0, 200, or 400 ppm for rats and 0, 100, or 200 ppm for mice. Male and female rats exposed to either 200 or 400 ppm developed statistically significant increases in mononuclear cell leukemias. According to the NTP report (NTP 1986b/Ex. 8-31, Appendix 4), the increased incidences of leukemias were responsible for the early deaths

observed in male and female rats exposed to perchloroethylene. At autopsy, most of the leukemias were determined to be in an advanced and probably fatal stage. Because of the effect of the leukemias on the early mortality of the exposed rats, a life-table analysis was used to test for the statistical significance of the findings; this analysis revealed that the increased incidence of leukemia was statistically significant in both low- and high-dose male rats and in low-dose female rats, and was marginally significant (p = 0.053) in high-dose female rats.

Male rats also developed a significant increase in renal tubular cell adenomas and carcinomas. Perchloroethylene induced a significantly increased incidence of hepatocellular carcinomas at both dose levels in mice of both sexes. The NTP Peer Review Panel concluded that there was "clear evidence of carcinogenicity of tetrachloroethylene" (perchloroethylene) in male rats and in male and female mice, and "some evidence" in female rats (Ex. 8–31, Appendix 4).

In addition, a number of human studies were submitted to the general industry rulemaking record that implicate perchloroethylene as a potential carcinogen (Ex. 8-31). Among these was a study by Brown and Kaplan (1987/Ex. 8-31, Appendix 6), which reported a statistically significant elevation in urinary tract cancer deaths among 1,690 dry cleaning workers exposed to perchloroethylene and other petroleum solvents. However, a subcohort of workers who used perchloroethylene as the primary solvent showed no increase in bladder cancer mortality. Brown and Kaplan concluded that "confounding exposure to petroleum solvents complicates any conclusions regarding the association between * * * [perchloroethylene] and cancer of the urinary tract" (Brown and Kaplan 1987/Ex. 8-31, Appendix 8, p. 540).

Katz and Jowett (1981/Ex. 8-31, Appendix 9) studied the mortality pattern of 871 female dry cleaning workers for the period 1963 through 1977. Elevated incidences of cancers of the kidney and genitals were reported, along with a smaller excess of bladder and skin cancers and lymphosarcomas. The authors concluded that, although results obtained with the methodology used (proportionate mortality ratios) require careful interpretation, "this study raises the possibility that exposure to dry cleaning fluids may increase the risk of certain cancers' (Katz and Jowett 1981/Ex. 8-31, Appendix 9, p. 510). The dry cleaning

fluids used by members of the cohort included carbon tetrachloride, trichloroethylene, and perchloroethylene.

Steinhagen et al. (1983/Ex. 8-31, Appendix 8) reported a significant excess of liver cancer among male workers in the laundry and dry cleaning industry in New Jersey. This study was a retrospective case-control study. The liver cancer cases were concentrated among individuals who processed clothes and were exposed to chemicals. The report did not identify the solvents in use (Steinhagen, Slade, Altman, and Bill 1983/Ex. 8-31, Appendix 8).

Duh and Asal (1984/Ex. 8-31,

Appendix 7) examined the mortality experience of 440 dry cleaning workers in Oklahoma for the period 1975 through 1981. Elevated standardized mortality odds ratios (SMORs) were found for both lung cancer (SMOR=1.7) and kidney cancer (SMOR=3.8) (Duh and Asal 1984/Ex. 8-31, Appendix 7). During the general industry rulemaking, the Amalgamated Clothing and Textile Workers Union (ACTWU) submitted a quantitative risk assessment conducted by Dale Hattis of the Center for Technology Policy and Industrial Development at the Massachusetts Institute of Technology (Hattis 1986/Ex. 8-31, Appendix 11-A) This work was conducted in 1986 for the National Institute for Environmental Health Sciences. Hattis used a pharmacokinetic model that incorporated species-specific rates of formation for the metabolites of perchloroethylene. Using the rat leukemia and mouse liver tumor data from the NTP (1986b/Ex. 8-31, Appendix 4) bioassay, Hattis obtained a "best estimate" of the lifetime cancer risk (for workers exposed at the former 100-ppm OSHA limit for 45 years to perchloroethylene) of 45 deaths per 1,000 workers. The best-estimate lifetime risks

workers, respectively. In its posthearing comments to the general industry rulemaking record, the Halogenated Solvents Industry Alliance (HSIA) (Ex. 186) discussed several aspects of the available data to support its contention that perchloroethylene should not be considered a probable human carcinogen. Specifically, the HSIA raised questions concerning the interpretation of epidemiologic data and the NCI gavage and inhalation studies. OSHA addressed each of these points in the preamble to the final general industry rule (54 FR 2686-2689) and concluded that the evidence for the

associated with 45 years of exposure to

50 and 10 ppm of perchloroethylene

were 27 and 6.4 deaths per 1,000

carcinogenicity of perchloroethylene "is convincing." Based predominantly on the animal data, NIOSH has also concluded that perchloroethylene is a potential human carcinogen; NIOSH judged the evidence for perchloroethylene's carcinogenicity sufficient to warrant a separate 6(b) rulemaking (Ex. 8-47, Table N6B). In 1987, the International Agency for Research on Cancer (IARC) also classified perchloroethylene as a Category 2B carcinogen (i.e., a substance for which the evidence in animals is sufficient). The EPA's SAB has determined that perchloro-ethylene is a Category C carcinogen (i.e., a possible human carcinogen, and a carcinogen in animals). In addition, a number of human studies suggest elevated cancer risks, particularly of the kidney and bladder, among workers exposed to perchloroethylene and other solvents in dry cleaning facilities.

Based on a review of all of the available evidence on perchloroethylene, including the testimony and briefs submitted by the parties during the rulemaking for general industry, OSHA concluded that perchloroethylene is a potential human carcinogen that presents a significant risk of material health impairment to workers exposed to it in their places of work. The Agency consequently set 25 ppm as the lowest limit for which there was evidence for feasibility. That standard is now in effect for general industry. The IFI and HSIA have challenged the 25 ppm PEL in court as being too low, and the AFL-CIO has challenged on the grounds that it is too high. The matter is now pending before the Eleventh Circuit Court of Appeals.

The risk assessment conducted by Hattis (1986/Ex. 8-31, Appendix 11-A) estimates that there is an excess lifetime cancer mortality risk of 45 deaths per 1,000 workers exposed for 45 years to the current 100-ppm TWA PEL. At the level of 50 ppm, Dr. Hattis estimated the excess lifetime risk to be 27 deaths per 1,000 workers. OSHA preliminarily concludes that this assessment and the underlying evidence indicate that a further reduction in the PEL is necessary. In the general industry rulemaking OSHA concluded that 25 ppm was the lowest level demonstrated by the available evidence to be feasible.

OSHA is proposing an 8-hour TWA PEL of 25 ppm for perchloroethylene in the construction, agriculture, and maritime industries. OSHA preliminarily concludes that this PEL will substantially reduce the significant risk of material impairment of health presented by exposure to this substance.

In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.
o-TOLUIDINE
CAS: 95-53-4; Chemical Formula:
CH₃C₆H₄NH₂
H.S. No. 1399

OSHA's 8-hour TWA limit for otoluidine in general industry and in the construction and maritime industries is 5 ppm. The Agency has no PEL in agriculture for this substance. The ACGIH identifies o-toluidine as a suspected human carcinogen (A2) and has assigned it a TLV®-TWA of 2 ppm, with a skin notation. NIOSH has no REL for o-toluidine but concurs (Ex. 8-47, Table N6A) with the limit being proposed. The International Agency for Research on Cancer (IARC 1982b, as cited in ACGIH 1986/Ex. 1-3, p. 586) classifies o-toluidine as a probable carcinogen (category 2A) based on sufficient evidence of its carcinogenicity in rats and mice following oral administration (IARC 1982b, as cited in ACGIH 1986/Ex. 1-3, p. 586). IARC judged the evidence inadequate to establish o-toluidine's carcinogenicity in humans. The Agency is proposing that its current PEL of 5 ppm as a TWA now be applied to the agriculture industry in addition to the construction and maritime industries and that a skin notation be added. This limit, and the skin notation, were recently reaffirmed for general industry.

o-Toluidine is a light yellow liquid that rapidly darkens on exposure to air and light. It is used in textile printing dyes, as a vulcanization accelerator, and in organic synthesis (Hawley's 1987, p.

o-Toluidine is of moderate acute toxicity; the oral LD50s in rats and mice are 670 mg/kg and 520 mg/kg, respectively. The dermal LD50 in rabbits is 3250 mg/kg (RTECS 1990). Acute exposure to o-toluidine causes methemoglobinemia and transient hematuria. The earliest manifestations of exposure are headache and cyanosis of the lips, mucous membranes, fingernail beds, and tongue; with continued exposure, symptoms include weakness and dizziness leading to stupor, unconsciousness, and death. Exposure to a 10-ppm concentration of o-toluidine for a short period of time may lead to symptoms of illness, and exposure to 40 ppm for an hour or more can cause severe toxic effects. Methemoglobinemia has been produced in experimental animals exposed to 6 to 23 ppm for several hours (Proctor, Hughes, and Fischman 1988, pp. 481o-Toluidine is mutagenic in short-term tests, inducing sister chromatid exchanges and unscheduled DNA synthesis in mammalian cells in vitro and chromosomal anomalies in yeast. o-Toluidine was negative in the micronucleus test in mice in vivo, but induced cell transformations in the BHK (baby hamster kidney) assay. IARC considers these data to be sufficient evidence of o-toluidine's activity in short-term tests (IARC 1982b).

There are a number of studies that report an excess of bladder tumors in dyestuff workers exposed to o-toluidine and other chemicals; however, there are no studies that examine a population of workers exposed to o-toluidine alone. Workers exposed to toluene, onitrotoluene, o-toluidine, and 4.4methylene bis (2-methylaniline) in manufacturing were observed to have an excess of bladder tumors. However, the concurrent exposures of these workers to these other potential carcinogens make these data inappropriate for use in the quantitative assessment of o-toluidine's carcinogenic risk in human populations. A few reports of bladder tumors in persons exposed primarily to o-toluidine have been reported, but insufficient follow-up time and incomplete data have prevented the establishment of a clear quantitative association between otoluidine exposure and cancer in humans. For this reason, IARC considers the data from human studies inadequate to establish an association between exposure to o-toluidine and cancer (IARC 1982b).

Several studies have been conducted that implicate o-toluidine as a potential carcinogen. In rats, statistically significant increases in subcutaneous fibromas, fibrosarcomas, and cancers of the urinary bladder have been reported. Studies in mice have resulted in statistically significant increases in hemangiosarcomas and hepatocellular carcinomas. For example, the National Cancer Institute (NCI 1979c, as cited in ACGIH 1986/Ex. 1-3, p. 586) conducted long-term carcinogenicity studies with otoluidine in rats and mice. Both of these studies were positive for carcinogenicity. The mouse study used groups of 50 female and 50 male B6C3F1 mice fed o-toluidine hydrochloride in the diet at levels of 1000 ppm or 3000 ppm for 102 to 103 weeks. There was no excess mortality in the tested animals. At the 3000-ppm dose level, there was a statistically significant increase in hemangiosarcomas at all sites in males and a statistically significant increase in hepatocellular carcinomas and adenomas in females.

The National Cancer Institute also conducted a 2-year feeding study with 50 male and 50 female Fischer 344 rats. There was a dose-related trend in mortality (which was not caused by cancer); all the males in the high-dose group died by week 100. However, the females at both dose levels were observed to have significant increases in transitional-cell carcinomas or papillomas of the urinary bladder, and the high-dose females developed fibroadenomas of the mammary gland. The males at both dose levels showed significant increases in fibromas of the subcutaneous tissue and mesotheliomas in multiple organs (NCI 1979c, as cited in ACGIH 1986/Ex. 1-3, p. 586). The high mortality in the males complicates the interpretation of these latter findings.

Weisburger, Russfield, Homburger et al. (1978/Ex. 1-535) reported positive findings for o-toluidine in long-term feeding studies in rats and mice. The study in rats was conducted with two groups of 25 male CD rats fed otoluidine in the diet on one of two regimens: 8000 ppm for three months and then 4000 ppm for an additional 15 months, or 16,000 ppm for three months and then 8000 ppm for an additional 15 months. Statistically significant increases in the incidence of subcutaneous fibromas and fibrosarcomas were observed in both dose groups. In addition, there was a nonstatistically significant increase in the incidence of transitional-cell carcinomas of the urinary bladder in these animals.

Weisburger, Russfield, Homburger et al. (1978/Ex. 1-535) also reported the results of a long-term study in mice. Groups of 25 male and 25 female CD-1 mice were fed diets containing otoluidine at two dose levels: 16,000 ppm for three months and then 8000 ppm for an additional 15 months, or 32,000 ppm for three months and then 8000 ppm for an additional 15 months. There was a statistically significant, dose-related increase in the incidences of vascular tumors (hemangiosarcomas and hemangiomas of the abdominal viscera) in both sexes of treated mice, compared with results in control mice.

Risk estimate for o-toluidine. Four of these carcinogenicity studies of o-toluidine have yielded sufficient and adequate data for quantitative risk estimation: The two NCI studies (NCI 1979c, as cited in ACGIH 1986/Ex. 1–3, p. 586) and the two Weisburger et al. (1978/Ex. 1–535) studies. OSHA used the NCI (1979c) study in rats as the basis for its quantitative risk assessment because it provides the most appropriate data. Table C14–9 presents the Maximum

Likelihood Estimates (MLEs) of excess deaths per 1,000 employees predicted to result from exposure to o-toluidine at the OSHA PEL of 5 ppm and at higher levels to illustrate the potential impact on risk of extending the 5 ppm PEL to agriculture. These data were calculated using a multistage model, GLOBAL83.

TABLE C14-9.—MULTISTAGE MODEL ES-JIMATES OF CANCER RISK ASSOCIATED WITH WORKING LIFETIME EXPOSURE TO 0-TOLUIDINE

Exposure Level	Excess cancer deaths per 1,000 workers			
	MLE	UCL		
50 ppm	1.48	16.0		
25 ppm	0.69	8.0 1.60		

MLE=Maximum likelihood estimate of risk. UCL=Upper-bound (95-percent) confidence limit on maximum likelihood estimate of risk.

Table C14-9 shows an excess MLE estimate of risk of 0.14 per 1,000 workers exposed over their working lifetimes at a PEL of 5 ppm; in contrast, lifetime exposure to 50 ppm is associated with estimated mortality risk levels exceeding 1 in 1,000 workers. Accordingly, OSHA has preliminarily concluded that it is appropriate to retain the existing 5-ppm TWA PEL and to add the skin notation for o-toluidine in the construction and maritime industries and to propose the PEL and skin notation for the agriculture industry as well; adoption of a 5 ppm limit in agriculture is necessary to substantially reduce the significant risk of material impairment of health that would exist in the absence of a limit. In addition. promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. p-TOLUIDINE CAS: 106-49-0; Chemical Formula:

CAS: 106-49-0; Chemical Formula: CH₂C₆H₄NH₂ H.S. No. 1400

OSHA has no PEL for p-toluidine in the construction, agriculture, and maritime industries. The ACGIH considers this substance a suspected human carcinogen (A2) and has assigned a TLV*-TWA of 2 ppm, and a skin notation, to p-toluidine. There is no NIOSH REL for this substance. OSHA is proposing a PEL of 2 ppm as an 8-hour TWA, with a skin notation, for p-toluidine in the construction, agriculture, and maritime industries. This is the limit recently established for this substance in general industry.

p-Toluidine is a white solid that is primarily used as an intermediate in the manufacture of dyes (ACGIH 1986, p. 590). p-Toluidine is somewhat more acutely toxic than the ortho isomer; the oral LD₅₀s in rats and mice are 656 and 330 mg/kg, respectively (RTECS 1984). p-Toluidine is a powerful methemoglobin former, causing anoxia with symptoms of headache, vertigo, and mental confusion. Acute exposures also cause microscopic or macroscopic hematuria, which clears upon cessation of exposure.

One study is available that investigates the carcinogenic potential of lifetime exposure to p-toluidine in experimental animals (Weisburger, Russfield, Homburger et al. 1978/Ex. 1-535). Male and female mice were exposed to p-toluidine in the diet for a total of 18 months. During the first six months of the experiment, mice were exposed to 1000 or 2000 mg p-toluidine/ kg diet. As a result of the weight loss that occurred in mice exposed to the 2000 mg/kg diet dose, the concentrations of p-toluidine were reduced to 500 and 1000 mg/kg diet during the last 12 months of exposure. The rate of food consumption by the animals was not reported but was assumed to be 3 g/day. Thus, the average doses of p-toluidine received during the 18-month exposure were calculated to be 80 and 160 mg/kg body weight per day (Weisburger, Russfield, Homburger et al. 1978/Ex. 1-

For both the low and high dietary doses of p-toluidine, a significant increase in the incidence of hepatomas was observed. The incidence of tumors in the control, 80, and 160 mg/kg/day groups were 3/38, 10/38, and 12/35, respectively. The same study (Weisburger, Russfield, Homburger et al. 1978/Ex. 1–535) showed negative results in male rats exposed to two doses of p-toluidine in the diet for 18 months (1000-and 2000-mg/kg diet).

Risk estimate for p-toluidine. To assess the quantitative risk of p-toluidine's carcinogenicity, OSHA used the Weisburger et al. (1978/Ex. 1–535) data which, despite some limitations (e.g., changes in dose levels during the experiment and the absence of data concerning the amount of food animals consumed during the exposure period), were considered adequate for risk assessment purposes.

The maximum likelihood estimates (MLE) of excess cancers per 1,000 workers over an occupational lifetime and the 95-percent upper-bound estimates were obtained by using a linearized multistage model (GLOBAL83). These values are summarized in Table C14–10. This table shows the number of cancer deaths potentially associated with working

lifetime exposure to 20, 5, or 2 ppm p-toluidine.

TABLE C14-10.—MULTISTAGE MODEL ES-TIMATES OF CANCER RISK ASSOCIATED WITH WORKING LIFETIME EXPOSURE TO P-TOLUIDINE

Exposure Level	Excess cancer 1,000 wo	deaths per orkers
	MLE	UCL
2 ppm*	12	19
5 ppm	29	46
20 ppm	112	172

* Proposed OSHA PEL in construction, maritime, and agriculture.

MLE = Maximum likelihood estimate of risk.

MLE = Maximum likelihood estimate of risk.

UCL = Upper-bound (95-percent) confidence limit
on maximum likelihood estimate of risk.

OSHA preliminarily concludes, as Table C14-10 shows, that workers in construction, maritime, and agriculture who are exposed to p-toluidine are at significant risk of developing hepatomas, an effect that the Agency considers material impairment of health. For example, the MLE at 20 ppm is 112 excess cancer deaths per 1,000 workers exposed over a working lifetime. Promulgating a PEL of 2 ppm will substantially reduce this significant risk of excess cancer deaths by 90 percent. During the general industry rulemaking, NIOSH (Ex. 8-47, Table N6B) judged the evidence on p-toluidine sufficient to warrant a separate 6(b) rulemaking. Additional data may support a further reduction in the PEL. OSHA is proposing an 8-hour TWA limit of 2 ppm for ptoluidine in the construction, agriculture, and maritime industries; a skin notation is included to protect against percutaneous absorption of this substance. The Agency believes this limit will significantly reduce the cancer risks associated with exposures to this substance at the levels permitted by the absence of a limit. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. VINYL BROMIDE

CAS: 593-60-2; Chemical Formula: C₂H₃Br

LIC 142E

OSHA has no PEL for vinyl bromide in the construction, agriculture, or maritime industries. NIOSH considers vinyl bromide a potential human carcinogen and recommends that all vinyl halides be controlled as specified for vinyl chloride, with an eventual goal of zero exposure. The ACGIH places vinyl bromide on its A2 list of industrial substances suspected of having carcinogenic potential in humans and has assigned it a TLV*-TWA of 5 ppm.

The Agency is proposing a PEL of 5 ppm as a TWA for vinyl bromide in the construction, agriculture, and maritime industries. This is the limit recently established for this substance in general industry.

Vinyl bromide is a colorless gas with a characteristic odor and is used as an intermediate in organic synthesis and in the manufacture of polymers, copolymers, and flame retardants. Its principal use is as a flame retardant.

The oral LD50 of a vinyl bromide/corn oil solution was found to be 500 mg/kg in rats. Inhalation by rats of a 100,000ppm concentration of vinyl bromide produced deep anesthesia and death in 15 minutes; however, when exposure was terminated prior to death, the animals recovered and survived. Exposure of rats to a 50,000-ppm concentration caused unconsciousness in 25 minutes and death in 7 hours; minor liver and kidney injury was observed in these animals. No histopathological changes were observed in rats exposed to a 25,000ppm concentration for 7 hours. In a subchronic study, no changes in food consumption, histopathology, or hematology were noted in rats, rabbits, and monkeys exposed to 250 or 500 ppm for 6 hours/day, 5 days/week, for 6 months (IARC 1979, Vol. 19, pp. 370-371; IARC 1986, Vol. 39, pp. 138-139).

Henschler and Hoos (1982/Ex. 1-818) believe that vinyl bromide undergoes the same mechanism of biotransformation as its structural analog, vinyl chloride, a recognized human carcinogen that has been regulated by OSHA in a Section 6(b) rulemaking. The microsomal oxidation of vinyl bromide leads to epoxide formation, which results, in turn, in the formation of a reactive intermediate. This intermediate has the potential to form covalent bonds with DNA to produce a mutagenic response. Vinyl bromide has been reported to be mutagenic in Salmonella typhimurium and tradescantia (IARC 1979a/Ex. 1-1125; NIOSH/OSHA 1978/Ex. 1-1119).

No epidemiological studies have been conducted on populations exposed to vinyl bromide. Benya, Busey, Dorato, and Berteau (1982/Ex. 1–244) reported a positive carcinogenic response in an inhalation study of rats exposed to vinyl bromide vapor; this study is important because inhalation is a major mode of occupational exposure. The results of the Van Duuren (1977/Ex. 1–284) study were equivocal (described below), in that female Swiss albino mice were exposed dermally or by subcutaneous injection either to vinyl bromide in

acetone or to polymerized vinyl bromide in an aqueous latex solution.

Benya et al. (1982/Ex. 1-244) exposed male and female Sprague-Dawley rats to 0, 9.7, 52, 247, or 1235 ppm vinyl bromide by inhalation for six hours daily, five days per week, for two years. The incidence of angiosarcomas, primarily of the liver, was found to be statistically significant in all dose groups tested except controls. It should be noted that a closely related chemical analog, vinyl chloride, also causes liver angiosarcomas in humans and animals. The combined incidences of hepatic angiosarcomas in the treated male and female rats were 1/288, 17/240, 86/240, 122/240, and 84/240 for these respective dose levels. One female rat in the control group developed an hepatic angiosarcoma. Table C14-11 summarizes the incidence of angiosarcoma in control and treated

Van Duuren (1977/Ex. 1-284) injected a group of female ICR/Ha Swiss mice once weekly for 48 weeks with 0.05 ml of commercial polymerized vinyl bromide aqueous latex suspension; the animals were observed for 420 days. Nineteen of the 30 mice developed sarcomas at the site of injection. Animals in a positive control group that had been injected with b-propriolactone (0.3 mg/.05 ml trioctanoin) developed 18 sarcomas and three squamous cell carcinomas (in 30 mice). No tumors developed in untreated controls or in controls injected with trioctanoin, an organic solvent, alone (Van Duuren 1977/Ex. 1-284).

In another injection study by the same author, a group of female IRC/Ha Swiss mice were treated with 25 mg vinyl bromide per animal in 0.05 ml trioctanoin once weekly for 48 weeks. The mice were observed for 420 days. One control group was given a weekly injection of trioctanoin alone and the other control group was untreated. No local tumors were seen in any of the test groups, although pathological examination of the animals appears to have been incomplete (Van Duuren 1977/Ex. 1–284).

Application of vinyl bromide to the skin of female ICR/Ha Swiss mice at a dose of 15 mg per animal administered in 0.1 ml of acetone three times weekly for 420 days resulted in no tumors. When this solution was applied once and was followed by an application of phorbol myristyl acetate (PMA) three times weekly, one of 30 mice developed a skin papilloma at 412 days, one control treated with PMA developed a tumor after 44 days, and no untreated controls

developed tumors (Van Duuren 1977/Ex. 1-284).

TABLE C14-11.-INCIDENCE OF ANGIOSARCOMAS IN CONTROL AND VINYL-BROMIDE-EXPOSED RATS

	F		Males	1		Females	
Group	level (ppm)	No. of animals	No. with angiosar-coma	р	No. of animals	No. with angiosar-coma	р
	Control	144	0		144	1	
2	10	120	7	< 0.025	120	10	< 0.01
3	50	120	36	< 0.001	120	50	< 0.001
f	250	120	61	< 0.001	120	61	< 0.001
5	1250	120	43	< 0.001	120	41	< 0.001

Source: Benya, Busey, Dorato, and Berteau (1982/Ex. 1-244).

In another dermal study, a dose of 0.1 ml of polymerized vinyl bromide in an aqueous latex suspension was applied three times weekly to the skin of female ICR/Ha Swiss mice for 420 days. No skin tumors developed. When this solution was applied once, followed by an application of PMA three times weekly, one of 30 mice developed a skin tumor at 175 days. No untreated controls developed skin tumors (Van Duuren 1977/Ex. 1–284).

Based on the studies cited above, IARC (1986, Vol. 39, pp. 137–142) concluded that there was sufficient evidence for the carcinogenicity of vinyl bromide in experimental animals, and classified vinyl bromide as a 2A

carcinogen.

Risk estimate for vinyl bromide. The Benya et al. (1982/Ex. 1-244) study was a well-designed and -conducted study that yielded sufficient information for quantitative risk estimation. The route of administration used in the study, inhalation, is directly applicable to occupational exposure, and the incidence of hepatic angiosarcoma was significant. Angiosarcoma is a rare and malignant neoplasm that has a very low background incidence in animals and humans. Therefore, its appearance in the exposed rats supports the premise that vinyl bromide is potentially carcinogenic in humans. Also, it is the same tumor that is associated with the exposure of workers and animals to vinyl chloride, a recognized human carcinogen and a compound whose structure is similar to that of vinyl

To estimate excess cancer risk over background incidence for a chemical, OSHA relied on the rat inhalation study by Benya et al. (1982/Ex. 1–244). Since both male and female rats responded equally to vinyl bromide treatment, data from the two groups were combined by calculating the geometric means of the risk estimates derived from the male and female response data (Anderson

1983/Ex. 1–1009). The high-dose data for each test group were dropped, since their inclusion makes the dose-response curve nonmonotonic and precludes proper fitting of the linearized multistage risk model (EPA 1984d).

Since cancer risk modeling assumes lifetime exposure, adjustments were made to fit the animal data to this criterion. The adjustments made for the data in the Benya et al. (1982/Ex. 1–244) study were: Multiplying dose by 5/7 to adjust for days of exposure per week and by 6/24 to adjust for hours of exposure per day. These adjusted doses were then changed to human equivalent doses.

Three hypothetical occupational exposure limits, 5 ppm, 20 ppm, and 250 ppm, were used to calculate the maximum likelihood estimates of risk of developing angiosarcoma of the liver. Five ppm is OSHA's limit in general industry. Twenty ppm was chosen as an intermediate exposure level, and 250 ppm was the ACGIH TLV® before the ACGIH reduced it in 1978. These occupational dose levels were also adjusted for lifetime exposure. The adjustments made were: multiplying dose by 5/7 to adjust for days worked per week, by 50/52 to adjust for vacation time, by 8/24 to adjust for hours of exposure per day, and by 45/70 to adjust for work years per lifetime.

Because inhalation is the primary route of exposure to vinyl bromide in occupational settings, the occupational dose was calculated assuming that air intake in humans is 20 m³ per 24-hour day (Anderson 1983/Ex. 1–1009). The fraction of vinyl bromide absorbed was assumed to be 100 percent, because no absorption rate data were available for vinyl bromide. Because the log p (lipid solubility) value for vinyl bromide (1.52) is similar to that for vinyl chloride (1.38), OSHA assumed that the absorption rates of these two compounds would also be similar. The absorption rate for

vinyl chloride used in risk estimations is assumed to be 100 percent (IRIS 1988).

The MLE shown in Table C14–12 for an occupational exposure to 250 ppm of vinyl bromide is 870 excess deaths per 1,000 workers. According to the linearized multistage risk model, 870 of 1,000 workers exposed over their working lifetimes to vinyl bromide at 250 ppm are at risk of developing angiosarcoma. The MLE for an occupational exposure to 5 ppm of vinyl bromide is 0.04; this indicates that, at the proposed PEL, 40 workers per 1,000 exposed to this substance over their occupational lifetimes are at risk of developing angiosarcoma.

TABLE C14-12—MULTISTAGE MODEL ES-TIMATES OF CANCER RISK ASSOCIATED WITH LIFETIME EXPOSURE TO VINYL BROMIDE

 Proposed PEL in construction, maritime, and agriculture.

Intermediate exposure level.

⁴ ACGIH limit before 1978. MLE = Maximum likelihood estimate of risk. UCL = 95-percent upper-confidence limit on maximum likelihood estimate on risk.

Table C14–12 indicates that workers exposed to this substance, which was formerly not regulated by OSHA in construction, maritime, or agriculture, are clearly at significant risk of developing hepatic angiosarcomas, the same rare type of tumor associated with exposure to vinyl chloride, a structurally similar substance. OSHA determined in its prior rulemaking on vinyl chloride that this disease constitutes a material impairment of health and functional capacity. At the present time, OSHA preliminarily concludes that establishing a PEL of 5 ppm TWA will substantially

reduce the significant risk of cancer potentially associated with exposure at higher levels formerly permitted in the absence of an OSHA limit for this substance in the construction, agriculture, and maritime industries. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

OSHA also concluded in the general industry rulemaking that there is a significant residual risk at vinyl bromide levels of 5 ppm. The AFL-CIO has challenged the 5 ppm limit as being too high in its petition to the Eleventh Circuit. OSHA has stated to the court that it will reevaluate the PEL for vinyl bromide in its first update of the Air Contaminants Standard. OSHA also preliminarily concludes that there is a residual significant risk associated with the proposed 5 ppm PEL for construction, maritime, and agriculture. However, the 5 ppm PEL provides substantially greater protection to workers than do the levels that could exist in the absence of a limit. OSHA believes that this rulemaking, whose principal purpose is to extend to all workers the increased protection that now exists in general industry, could not be completed in a reasonable period if extensive additional information had to be obtained and analyzed to determine what lower level was feasible and necessary to further reduce the risk. Accordingly, in the first Air Contaminants update, OSHA will also consider for construction, maritime, and agriculture whether a lower limit is appropriate for vinyl bromide.

VINYL CHLORIDE

CAS: 75-01-4; Chemical Formula:

CH₂=CHCL

H.S. No. 2167

In general industry, construction, and maritime, OSHA's permissible exposure limit for vinyl chloride (VC) is 1 ppm as an 8-hour TWA and 5 ppm as a 15minute STEL. In addition, no employee may be exposed to vinyl chloride by direct contact with this substance in liquid form. There is no limit in agriculture. The ACGIH designates vinyl chloride an A1 carcinogen and assigns it a TLV*-TWA of 5 ppm. NIOSH considers VC a potential human carcinogen and recommends that exposure be reduced to the lowest feasible level. OSHA is proposing an 8hour TWA PEL of 1 ppm and a 15minute STEL of 5 ppm in agriculture. Promulgation of these limits will make the PELs for VC consistent across all OSHA-regulated sectors.

Vinyl chloride (chlorethene) is a synthetic organic chemical made from ethylene or acetylene and chloride by any one of several processes. It is the parent compound of a series of thermoplastic resin polymers and copolymers which are widely used for containers, wrapping film, electrical insulation, pipe, conduit, and a variety of other industrial and consumer products. Vinyl chloride is used primarily in the production of polyvinyl chloride (PVC), a resin which is produced through batch processing. The conversion of the VC monomer into a polymer or copolymer is an incomplete process, i.e., not all of the monomer is reacted.

The carcinogenicity of vinyl chloride for three animal species (rat, mouse, hamster) has been documented by Maltoni. Moreover, Maltoni's investigations have demonstrated a dose-dependent relationship for the induction of tumors (i.e., more tumors occur at higher exposure levels), including angiosarcoma of the liver, in rats. Of 200 mice (100 males, 100 females) exposed to 50 ppm of vinyl chloride by inhalation for eleven months, 100 died. Sixty-four animals died without gross postmortem pathologic examination being performed. Of the 36 remaining animals for which a gross postmortem pathologic examination was performed, 13 (36 percent) were found to have liver tumors (including angiosarcomas), 21 (58 percent) lung tumors, 9 (25 percent) skin tumors, and one had a kidney tumor. A similar relationship has been demonstrated in both rats and mice. These investigators have induced angiosarcoma of the liver in rats and mice at exposure concentrations of 50 ppm, and in hamsters at higher concentrations of exposure. Additional tumors involving other organs, including the kidneys, lungs, and skin of exposed animals, were also observed in frequencies much in excess of these in control animals.

According to the 1970 report by the Surgeon General's Ad-Hoc Committee on the Evaluation of Low Levels of Environmental Chemical Carcinogens, the finding of cancer in two or more animal species may be extrapolated to indicate a carcinogenic hazard to humans. Here, such a finding was made in three species that were exposed to VC by inhalation, a route comparable to employee exposure. In addition, there were at least 13 confirmed cases of angiosarcoma of the liver among employees exposed to VC, a particularly significant number in view of the extreme rarity of this cancer in the U.S. adult male population (testimony of Dr. Marcus Key, Director of NIOSH, at the 1974 rulemaking hearing).

The findings of angiosarcoma of the liver in both experimental animals and exposed employees is compelling evidence that exposure of humans to vinyl chloride induces this tumor. Industry spokesmen, at the Agency's 1974 hearing, conceded that VC is carcinogenic in humans (e.g., testimony of Dr. McBurney, VC rulemaking hearing, Tr. 1041). Accordingly, it is concluded that VC must be regarded as a human carcinogen and the probable causal agent of angiosarcoma of the liver, and that exposure of employees to VC must be controlled.

Additional evidence of tumor induction in a variety of other organs, including lung, kidney, brain, and skin, as well as non-malignant alterations, such as fibrosis and connective tissue deterioration, indicates additional oncogenic and toxicologic properties of vinyl chloride.

Based on this evidence in humans and animals, OSHA concluded in the VC rulemaking that exposure to VC causes cancer in humans and animals. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed limits of 1 ppm as an 8-hour TWA and 5 ppm as a 15-minute STEL are necessary to substantially reduce these risks of material health impairment among these workers. Promulgation of these limits will make the PELs for VC consistent all OSHA-regulated sectors.

VINYL CYCLOHEXENE DIOXIDE CAS: 106-87-6; Chemical Formula: C₈H₁₂O₂ H.S. No. 1426

OSHA has no PEL for vinyl cyclohexene dioxide (VCD) in the construction, agriculture, and maritime industries. The ACGIH classifies VCD as a suspected human carcinogen (A2) and has assigned it a TLV*-TWA of 10 ppm, with a skin notation. NIOSH has no REL for this substance but concurs (Ex. 8-47, Table N6A) with the limit being proposed. OSHA is proposing a 10 ppm TWA PEL, with a skin notation, for this substance in the construction, agriculture, and maritime industries. This is the limit recently established in general industry.

Vinyl cyclohexene dioxide is a colorless liquid used as a chemical intermediate and as a monomer in the manufacture of polyglycols containing unreacted epoxy groups (Hine, Rowe, White, Darmer, and Youngblood 1981/Ex. 1–976). It is also used as a reactive diluent for other diepoxides and certain epoxy resins (IARC 1976).

Vinyl cyclohexene dioxide is a mild acute toxin when ingested; the oral LD₅₀ in rats has been reported to be 2.8 g/kg (ACGIH 1986, p. 627) and the LC₅₀ in rats for a 4-hour inhalation period is 800 ppm (RTECS 1990). Dermal exposure to this substance has caused mild-to-moderate skin irritation in workers, with occasional instances of marked skin irritation. Vinyl cyclohexene dioxide can be absorbed through the skin in significant amounts; the dermal LD₅₀ in rabbits is 0.62 mg/kg (ACGIH 1986, p. 627).

Turchi, Bonatti, Citti et al. (1981/Ex. 1–282) assayed the mutagenicity of VCD and several other epoxides using the TA100 strain of S. typhimurium and V79 Chinese hamster cells; these authors also investigated the alkylating properties of these chemicals. VCD tested positive in both the S. typhimurium test (point mutation) and the V79 Chinese hamster cell test (both point mutation and chromosome aberration), and had an intermediate alkylating capacity relative to other epoxide compounds tested.

There are no data concerning the adverse health effects of VCD in humans. There are no reports as a result of industrial experience that reveal carcinogenic effects in workers caused by VCD exposure (ACGIH 1986/Ex. 1–3).

Four studies have reported the development of skin tumors in mice exposed dermally to VCD (Hendry, Homer, and Rose 1951/Ex. 1–250; Kotin and Falk 1963/Ex. 1–287; Weil, Condra, Haun, and Streigel 1963/Ex. 1–257; and Van Duuren, Nelson, Orris, Palmes, and Schmitt 1963/Ex. 1–288). The study of Van Duuren et al. (1963/Ex. 1–288) included controls and is thus particularly well suited for an evaluation of VCD's carcinogenic potential.

These authors painted 30 male Swiss ICR/Ha mice with 0.1 ml of a 10-percent solution of VCD in benzene three times per week (approximately 100 mg of solution per application). Two negative controls were used; one set of 150 mice was treated with benzene alone and another set of 207 mice was not treated with anything. Fourteen of the 30 VCDtreated mice developed skin tumors after an undefined length of time (mean survival time was 326 days). The incidences of skin tumors in the controls were 11/150 and 13/207 for the benzenetreated and untreated mice, respectively. The incidence of skin tumors in the VCD-treated mice was significantly greater (reported in terms of a total tumor index rather than number of tumors) than the incidence observed in either of the controls (Van

Duuren, Nelson, Orris, Palmes, and Schmitt 1963/Ex. 1-288).

A recent study by the NTP reported that skin tumors developed in rats exposed to 31.5 g/kg applied to the skin for 2 years. In addition, this same study reported that vinyl cyclohexene dioxide induced mutations in mouse lymphocyte cells and sister chromatid exchanges in hamster ovary cells when administered in situ (RTECS 1990).

The studies of Van Duuren et al. (1963/Ex. 1-288) and the NTP (RTECS 1990) demonstrate the carcinogenicity of VCD in experimental animals. OSHA considered the possibility of conducting a quantitative risk assessment for VCD, but the Agency preliminarily concluded that the dose-response data in this study are unsuitable for quantitative risk assessment purposes because the VCD was administered in a solution of benzene, which is itself regulated as a carcinogen and classified as such by several authorities (IARC, NTP, NIOSH, and ACGIH). Even though the Van Duuren et al. (1963/Ex. 1-288) study included a control for the independent carcinogenic effects of benzene, the possibility of a synergistic or additive effect of benzene on VCD cannot be completely ruled out.

Vinyl cyclohexene dioxide has been shown to be carcinogenic by dermal application in mice, and four studies have confirmed these effects. Based on these animal studies showing VCD's carcinogenicity, OSHA preliminarily concludes that exposed employees in agriculture, construction, and maritime are at significant risk of cancer from exposure to VCD at the levels permitted by the absence of an OSHA limit. The Agency considers this effect a material impairment of health and preliminarily concludes that a 10 ppm 8-hour-TWA PEL, with a skin notation, is necessary to substantially reduce the significant occupational risk confronting VCDexposed employees in these sectors. In addition, promulgation of this limit will

consistent across all regulated sectors. Preliminary Conclusions for this Group of Substances. The Supreme Court in I.U.D. v. A.P.I. (supra, the Benzene decision) gave OSHA directions as to its decisional process; that case involved a carcinogen. OSHA is using the Supreme Court's guidance within the context of this present broader rulemaking. OSHA is also using the approach it has taken in the regulation of arsenic, benzene, EtO, asbestos, and formaldehyde; this approach has been upheld in the Courts of Appeals (see the introduction to this section). For the substances in this section, OSHA has either (1) already

make OSHA's PEL for this substance

conducted (in the case of substancespecific Section 6(b) standards), or (2) considered conducting quantitative risk assessments for each chemical discussed in this section. When adequate dose-response data were available, OSHA performed quantitative appraisals of the significance of the risk, either in the substance-specific rulemakings, the general-industry Air Contaminants rulemaking, or the present rulemaking. These risk assessments follow the approach OSHA has used in prior rulemakings for carcinogens, a process that has repeatedly been upheld by the courts.

OSHA conducted its significant risk analyses using the principles suggested by the Supreme Court and adopted in its carcinogen rulemakings subsequent to I.U.D. v. A.P.I. OSHA has proposed to establish new or revised exposure limits based on these analyses when they demonstrated that significant risk existed at the former PEL (if any) and that the new limit would substantially reduce significant risk and represent a feasible limit.

In some cases, the available data were not sufficient to conduct quantitative estimates of cancer risk at the same level of detail as in other cases. In these cases, OSHA believes that the analyses performed demonstrate that the new limits are necessary to reduce a significant risk of cancer mortality among workers in construction, maritime, and agriculture.

Overall, OSHA believes its analyses of the proposed new or revised limits for carcinogenic chemicals meet the Agency's legal requirements. OSHA preliminarily concludes that these limits will lead to substantial reductions in the significant risk of material impairment of health among workers in these sectors and are additionally feasible to attain.

15. Substances for Which 1987–1988 ACGIH TLV*s are Less Stringent Than Existing OSHA PELs

OSHA is eliminating this category, which appeared both in the proposed (53 FR 20961 et seq.) and final (54 FR 2332 et seq.) rules for Air Contaminants in general industry. In re-evaluating this category of substances, which included those for which the TLV's were less stringent than the corresponding OSHA PELs, the Agency has made a determination that these substances should be reassigned to other categories based on the health effects that provide the basis for establishing their respective limits. These substances have accordingly been reassigned to the following categories:

Substance	New category
Camphor (synthetic)	Sensory Irritation.
Copper fumes (measured as Cu).	Sensory Irritation.
1,1-Dichloroethane	Liver Toxicity.
Fluorine	
Hexachloroethane	Sensory Irritation.
Nickel carbonyl	Cancer.
Rhodium, metal fume & insoluble salts (measured as Rh).	Sensitization.
Silica, amorphous, diatomaceous earth.	Respiratory Effects.
Silica, amorphous, precipitate & gel.	Respiratory Effects.
Silver, metal dust & fume (measured as Ag).	Systemic Effects.
Tetraethyl lead	Systemic Effects.
Tetramethyl lead	Systemic Effects.
Uranium, soluble compounds (measured as U).	Kidney Effects.

16. Substances for Which OSHA is Proposing to Establish Short-Term Exposure Limits

Introduction. OSHA is proposing to establish a short-term exposure limit (STEL) for a total of 116 substances; these substances are listed in Table C15–1. OSHA is proposing these PELs for the construction, maritime, and agriculture industries. These STELs were recently adoped in general industry and thus promulgation in the construction, maritime, and agriculture sectors will make these STELs consistent across all OSHA-regulated sectors.

When OSHA adopted the 1970 ACGIH TLV*s for the construction and maritime industries, the ACGIH had not established the short-term TLV* category; as a consequence, none of the limits currently in effect in these industries have STELs. (However, some of the substances on OSHA's previous Z-2 table, whose limits derive from standards established by the American National Standards Institute rather than the ACGIH, have "acceptable ceiling concentrations" that act, in effect, as short-term exposure limits.)

The ACCIH defines a STEL as: a 15-minute time-weighted average exposure which should not be exceeded at any time during a work day even if the eight-hour time-weighted average is within the TLV³. Exposures at the STEL should not be longer than 15 minutes and should not be repeated more than four times per day. There should be at least 60 minutes between successive exposures at the STEL. An averaging period other than 15 minutes may be recommended when this is warranted by observed biological effects (ACGIH 1991).

TABLE C16-1.—SUBSTANCES FOR WHICH OSHA IS PROPOSING TO ESTABLISH STELS TO SUPPLEMENT TWA LIMITS IN CONSTRUCTION, MARITIME, AND AGRICULTURE

	H.S. number/chemical name	CAS No.	Proposed STEL
1001	Acetaldehyde	75-07-0	150 ppm.
1004	Acetone	67-64-1	1000 ppm.
005	Acetonitrile	75-05-8	60 ppm.
007	Acrolein	107-02-8	0.3 ppm.
010	Allyl alcohol	107-18-6	4 ppm.
111	Allyl chloride	107-05-1	2 ppm.
112	Allyl glycidyl ether (AGE)	106-92-3	10 ppm.
113	Allyl propyl disulfide	2179-59-1	3 ppm.
22	Ammonium chloride fume	12125-02-9	20 mg/m³.
142	Bromine	7726-95-6	0.3 ppm.
145	2-Butanone (MEK)	78-93-3	300 ppm.
147	n-Butyl acetate	123-86-4	200 ppm.
50	tert-Butyl alcohol	75-65-0	150 ppm.
56	p-tert-Butyltoluene	98-51-1	20 ppm.
64	Caprolactam Dust.	105-60-2	3 mg/m³.
65	Caprolactam Vapor	105-60-2	40 mg/m ³ .
69	Carbon dioxide	124-38-9	30,000 ppm
70	Carbon disulfide	75-15-0	12 ppm.
72	Carbon tetrabromide	558-13-4	0.3 ppm.
74	Carbonyl fluoride	353-50-4	5 ppm.
78	Chlorinated camphene	8001-35-2	1 mg/m ³ .
79	Chlorine.	7782-50-5	1 ppm.
80	Chlorine dioxide	10049-04-4	0.3 ppm.
89	o-Chiorostyrene	2039-87-4	75 ppm.
14	Decaborane	17702-41-9	0.15 ppm.
16	Di-sec-octyl-phthalate	117-81-7	10 mg/m ³ .
19	Dibutyl phosphate		2 ppm.
22	1,3-Dichioro-5,5-dimethylhydantoin	118-52-5	0.4 mg/m ³ .
25.	p-Dichlorobenzene.	106-46-7	110 ppm.
27	Dichloroethyl ether	111-44-4	10 ppm.
37	Diethylamine	109-89-7	25 ppm.
43	Dimethylaniline	121-69-7	10 ppm.
49	Dipropylene glycol methyl ether	34590-94-8	150 ppm.
59	Ethanolamine	141-43-5	6 ppm.
61	Ethyl acrylate	140-88-5	25 ppm.
62	Ethyl benzene	100-41-4	125 ppm.
63	Ethyl bromide	74-96-4	250 ppm.
64	Ethyl ether	60-29-7	500 ppm.
68	Ethylene dichloride	107-06-2	2 ppm.
77	Ferrovanadium dust	12604-58-9	3 mg/m³.
82	Formamide	75-12-7	30 ppm.
84	Furturyl alcohol	98-00-0	15 ppm.
85	Gasoline	8006-61-9	500 ppm.
94	n-Heptane	142-82-5	500 ppm.
01	Hexane isomers	Varies	1000 ppm.
03	Hexone (Methyl isobutyl ketone)	108-10-1	75 ppm.
80	Hydrogen fluoride	7664-39-3	6 ppm.
209	Hydrogen suffide	7783-06-4	15 ppm.
16	Iron pentacarbonyl	13463-40-6	0.2 ppm.

		7440-67-7	10 mg/m ³ .

Reasons for ACGIH STELs. The ACGIH establishes STELs for substances that cause a wide variety of acute effects; these effects include irritation, narcosis, lung damage, systemic effects, and organic poisoning. The ACGIH first considered adding

STELs to the TLV*-TWAs for some substances in 1971, when it appointed a subcommittee to study the appropriateness of adding such exposure limits to the TLV* list.

În 1973, this subcommittee recommended that the ACGIH establish

STELs as a third category (along with TLV®-TWAs and TLV® ceilings) of exposure limits. The STEL was defined as the maximum concentration to which workers can be exposed continuously for a period of up to 15 minutes without suffering from

1. Intolerable irritation.

2. Chronic or irreversible tissue

change, or

3. Narcosis of sufficient degree to increase accident proneness, impair self-rescue, or materially reduce work efficiency (Supplemental Documentation to the Fourth Edition of the Documentation of the Threshold Limit Values, ACGIH 1984).

The ACGIH stipulated that no more than four such excursions per day were permissible, with at least 60 minutes between exposure periods, and, that these excursions could not cause the daily TLV*-TWA to be exceeded.

In 1974, the ACGIH agreed by consensus that 425 of the 520 compounds in its 1973 list should have STELs assigned to them, but these were not in fact published until 1976, when "Tentative Values" for STELs were listed in the organization's annual booklet. The 1987-1988 ACGIH TLV® booklet states that the TLV*-STEL is "the concentration to which workers can be exposed continuously for a short period of time without suffering from (1) Irritation, (2) chronic or irreversible tissue damage, or (3) narcosis of sufficient degree to increase the likelihood of accidental injury, impair

self-rescue or materially reduce work efficiency . . . provided that the daily TLV*-TWA is not exceeded."

In 1982, the ACGIH limited the conditions calling for STELs to "[those situations] where toxic effects have been reported from high short-term exposures in either humans or animals." Since that time, the ACGIH has reexamined the toxicological data and subsequently deleted the STELs for several hundred substances because, in the opinion of the ACGIH, there was insufficient evidence that acute exposures to elevated levels of these substances caused adverse effects. The ACGIH has stressed that STELs should be set on physiological grounds rather than in response to sampling and analytical limitations (ACGIH 1984).

In addition to the STEL category, the ACGIH in the 1970s established a fourth limit, a general "excursion factor" that should always be observed implicitly but is not specifically assigned to each chemical. The "excursion limit" recommended by the ACGIH:

should exceed three times the TLV-TWA for no more than a total of 30 minutes during a work day and under no circumstances should they exceed five times the TLV-TWA. provided that the TLV-TWA is not exceeded (ACGIH 1987).

The basis for this excursion limit is good industrial hygiene practice: any process that has emissions that exceed the concentrations permitted by this excursion factor is not under good industrial hygiene control, and the ACGIH believes that, in such cases. efforts should be made to restore control (ACGIH 1991). Where a specific STEL exists for a substance, the specific STEL takes precedence over the general excursion limit (ACGIH 1987). Thus all ACGIH TLV*-TWAs have implicit excursion limits, but only a few substances (i.e., those for which specific toxicological evidence indicates that a STEL is necessary) have explicit STELs.

Basis for Short-Term Limits Being Proposed by OSHA. The STELs being proposed by OSHA in this rulemaking, which parallel those STELs remaining in the ACGIH's most recent list (ACGIH 1990–1991) are thus limits for substances for which there is toxicological evidence that short-term high exposures cause recognized acute effects. The health effects associated with short-term exposures to some of these substances are shown in Table C15–2.

TABLE C16-2.—HEALTH EFFECTS SUPPORTING PROPOSED STELS

	H.S. number/chemical name	Proposed STEL	Health effects
1001	Acetaldehyde	150 ppm	Eye irritation; narcosis; potential injury to respiratory tract.
1004	Acetone	1000 ppm	Eye, nose, and throat irritation; narcosls.
1005	Acetonitrile	60 ppm	Nausea; headache; convulsions.
1007	Acrolein		Irritation; lung edema.
1010	Allyl alcohol		
1011	Allyl chloride	2 ppm	
1012	Allyl glycidyl ether (AGE)		
1013	Allyl propyl disulfide	3 ppm

254	Methyl chloride		Narcosis.
255	Methyl chloroform (1,1,1-trichloroethane)		Anesthesia.
258	Methyl formate	150 ppm	Visual disturbances (temporary blindness); narcotic symptom mucous membrane irritation; dyspnea.
261	Methyl isobutyl carbinol	40 ppm	Eye irritation.
267	alpha-Methyl styrene		Eye irritation.
270	o-Methylcyclohexanone		Eye and respiratory irritation.
281	Morpholine		Irritation and harmful effects to eyes and vision.
282	Naphthalene	III I STORY AND A STORY OF THE PROPERTY OF THE	Ocular effects.
286	Nitric acid		
296			Respiratory Irritation.
	Octane	III PARTICULAR CONTROL OF THE PROPERTY OF THE PARTY OF TH	Acute effects on nervous system.
298	Osmium tetroxide	0.006 mg/m ³	Irritation; conjunctivitis.
299	Oxalic acid		Severe local burns to eyes, mucous membranes, and sk
301	Ozone		Pulmonary congestion; eye, nose, and throat irritation.
304	Pentaborane	0.015 ppm	Central nervous system effects.
306	Pentane	750 ppm	Narcotic and irritative effects.
307	2-Pentanone (MPK)	250 ppm	Narcotic effects; irritation.
309	Perchloryl fluoride		Respiratory irritation; fluorosis.
317	Phenylhydrazine		Sensitization effects.
319	Phorate (Thimet)		Cholinesterase inhibition.
320	Phosdrin (Mevinphos)		Cholinesterese inhibition.
321	Phosphine		Pulmonary irritation.
322	Phosphoric acid		
324	Phoenhous acreavilida		Respiratory irritation.
325	Phosphorus pentasulfide		Respiratory irritation.
	Phosphorus trichloride	A CONTRACTOR OF THE PARTY OF TH	Respiratory imitation.
338	n-Propyl acetate		Irritation; narcosis.
339	Propyl alcohol	250 ppm	Possible deep narcosis.
340	n-Propyl nitrate	40 ppm	Irritation; headache, nausea.
341	Propylene dichloride	110 ppm	Eye irritation; central nervous system effects.
343	Propylene glycol monomethyl ether	150 ppm	Eye irritation.
346	Resorcinol	20 ppm	Eye and skin irritation.
366	Sodium Fluoroacetate	0.15 mg/m ³	Metabolic inhibition.
372	Styrene, monomer	100 ppm	Tremors with subsequent severe convulsions; pulmonary eder may follow severe single exposure.
375	Sulfur dioxide	5 nom	
379	Sulfuryl fluoride	5 ppm	Respiratory effects.
387	Tetrahydrofigan	-10 ppm	Central nervous system effects; pulmonary irritation.
397	Tetrahydrofuran	250 ppm	Narcotic and irritative effects.
398	Toluene		Impairment of coordination, momentary memory loss, anores
	Toluene-2,4-diisocyanate	0.02 ppm	Sensitization effects.
400	1,1,2-Trichloro-1,2,2-tri-fluoroethane	1250 ppm	Impairment of psychomotor performance.
400	Trichloroethylene	200 pom	Narcosis.
408	i netnytamine	15 ppm	Acute irritation of eyes, mucous membranes, and lungs.
411	i nmetnylamine	15 ppm	Irritation.
424	VIIIYI acetate	20 nom	Irritation.
428	vinylidene chloride	20 nnm	Overt toxicity.
4308	. 1430b Wood dust, all soft and hardwoods, except Western red cedar	10 mg/m³	Respiratory effects.
431	Xylene (o,m,p-isomers)		
435	Zinc chloride (fume)	150 ppm	Narcosis, irritant effects.
	Zinc oxide turne	2mg/m³	Respiratory irritation.
		10 mg/m ³	Metal fume fever.

OSHA believes that the STELs and ceilings being proposed reflect the

concerns expressed by many in the previous rulemaking that short-term

limits be promulgated when a toxicologic basis exists for the short-

term limit. In general, OSHA is proposing STELs or ceiling limits when the toxicologic evidence for a particular substance indicates that the 8-hour TWA PEL alone would be insufficient to protect employees from experiencing adverse effects related to short-term exposure to elevated concentrations of that substance.

OSHA has not proposed establishing a general excursion limit, such as that recommended by the ACGIH, that applies to all regulated substances. However, there are workplace situations where OSHA believes that worker protection requires the implementation of a STEL. For example, OSHA believes that the severity of the health effect caused by exposure and the pattern of exposure prevalent in operations involving a given substance are both factors that should be considered when determining whether a short-term limit is appropriate. OSHA preliminarily concludes that, in these instances, promulgating a STEL is a necessary and appropriate measure for ensuring that workplace conditions will be maintained under a sufficient degree of control to ensure that workers are protected from experiencing serious exposure-related health effects.

17. Substances for Which OSHA Is Proposing to Add Skin Designations

For many of the substances included in this rulemaking, OSHA is proposing either to retain or to add skin designations in recognition of the capacity of these substances to be absorbed through the skin in sufficient quantities to cause toxic effects. Ninetyeight of these substances already have skin designations that apply in the maritime and construction sectors, and OSHA is proposing to add skin designations for an additional 42 substances in these sectors. In agriculture, where OSHA has previously not had limits, skin designations for all 140 substances are being proposed. Table C17-1 shows all of the substances for which the Agency is proposing to establish skin designations; those substances with asterisks already have skin designations in construction and maritime.

The ACGIH began to include skin designations for the chemicals in its list for the first time in 1961 (Stokinger 1962/Ex. 1-998). At that time, the organization stated that:

This notation is to be interpreted simply as an indicator that skin absorption may contribute to the overall intake from exposure in addition to that from inhalation. It refers mainly to absorption from liquid contamination (Stokinger 1962/Ex. 1-998).

The ACGIH has expanded on its reasoning since the 1960s, and the preface to the most recent Threshold Limit Values and Biological Exposure Indices for 1987-1988 (ACGIH 1990) explains that the skin designation is designed to call attention to the need for "appropriate measures for the prevention of cutaneous absorption so that the threshold limit is not invalidated." Thus, a skin notation warns that exposure via the cutaneous route, including absorption through the eyes or mucous membranes, may contribute substantially to an employee's overall exposure and cause systemic toxicity.

^{*} Skin designations for these substances already apply in the construction and maritime industry sectors. In these cases, OSHA is proposing to apply skin designations for these substances in the agricultural industry sector as well.

Biological Exposure Indices for 1987–1988 (ACGIH 1990) explains that the skin designation is designed to call attention to the need for "appropriate measures for the prevention of cutaneous absorption so that the threshold limit is not invalidated." Thus, a skin notation warns that exposure via the cutaneous route, including absorption through the eyes or mucous membranes, may contribute substantially to an employee's overall exposure and cause systemic toxicity.

The ACGIH has a policy of using a dermal LD₅₀ of 2 g/kg as a general cutoff for determining when to classify a substance as sufficiently absorbable to present a hazard via the percutaneous route; that is, substances having a single-dose dermal LD₅₀ of less than 2 g/kg receive a skin notation, while those with dermal LD₅₀s above this cutoff do not (ACGIH 1986/Ex. 1-3, p. 332). The Documentation (ACGIH 1986/Ex. 1-3) contains no cutoff value for chronic dermal exposures (i.e., for toxicity resulting from repeated applications of substances to the skin).

OSHA is proposing to include as paragraph 3[2] of the standard the following language regarding the use of skin notations:

An employee's skin exposure to substances listed in Table Z-1-A with the designation "Skin" following the substance name shall be prevented or reduced to the extent possible

through the use of gloves, coveralls, goggles, or other appropriate personal protective equipment, engineering controls or work practices.

OSHA is not proposing to require that engineering controls be used preferentially to protect against skin absorption; the Agency notes that this policy is consistent with 29 CFR 1910.132 and 1910.134, which require the use of engineering controls and work practices in preference to personal protective equipment only when inhalation is the route of entry. The proposed regulatory language that appears here is the same as that adopted in the 1989 Air Contaminants rulemaking for general industry.

As explained in the previous rule, OSHA believes that dermal irritation alone should not warrant a skin designation; instead, OSHA believes that skin designations should be used only in instances where a substance can be percutaneously absorbed in quantities sufficient to cause systemic poisoning. OSHA's decision logic for establishing skin notations derives from the Agency's Hazard Communication Standard (29 CFR 1910.1200). Appendix A of that regulation defines, in measurable terms, the possible health effects that may occur in the workplace as a result of chemical exposures. These definitions set forth quantitative guidelines for determining if chemicals are "highly toxic" or merely "toxic" by the dermal route of exposure. A chemical is considered highly toxic via skin absorption if

* * * [it] has a median lethal dose (LD50) of 200 milligrams or less per kilogram of body weight when administered by continuous contact for 24 hours (or less if death occurs within 24 hours) with the bare skin of albino rabbits weighing between two and three kilograms each.

It is considered *toxic* via skin absorption if

* * * [it] has a median lethal dose [LD $_{50}$] of more than 200 milligrams per kilogram but not more than 1,000 milligrams per kilogram of body weight when administered by continuous contact for 24 hours (or less if death occurs within 24 hours) with the bare skin of albino rabbits weighing between two and three kilograms each.

Accordingly, OSHA has preliminarily determined that a skin notation is necessary for substances that have median lethal dose (LD₅₀) values in rabbits on single-dose applications of less than 1000 mg/kg. In addition, in very rare cases where available data (for any species) indicate that dermal contact results in a systemic dose that is equivalent to or greater than the dose that would be permitted by the PEL via inhalation, OSHA believes that a skin designation is warranted. In addition to

this animal evidence, OSHA believes that the availability of human data demonstrating that systemic injury has occurred as a result of skin absorption is sufficient evidence that a skin notation is warranted. OSHA followed these guidelines in establishing skin designations in the recent rulemaking for general industry and has continued to observe them in the present rulemaking. Promulgation of these skin designations will thus make OSHA's skin designations consistent across all OSHA-regulated sectors.

V. Preliminary Regulatory Impact Analyses

A. Executive Summary

Affected Industries

The proposed standard addresses employee exposures to airborne substances in the construction, agriculture, and maritime industries. It should be noted that the use of EPA labelled pesticides pursuant to the label is regulated by the Environmental Protection Agency and therefore is not covered by this standard. Proposed PELs for asphalt fume, fibrous glass, and mineral wool would cover exposures to these substances in all industry sectors.

Activities with potential exposures are common in the construction industry; most firms in SICs 15, 16, and 17 would be affected to some degree. In the maritime industry, the proposed standard would affect establishments involved in shipbuilding and repair and in cargo handling operations. In the agriculture industry, firms likely to be affected include those engaged in silo operations, cotton ginning, and grape harvesting. Potentially affected firms in general industry would include those producing and using fibrous glass and mineral wool, asphalt, paving mixtures, and asphalt roofing products.

Employee Exposures and Benefits

In the construction industry, activities involving potential exposures above the proposed PELs include painting; concrete sealing and coating; abrasive blasting; sanding; batch mixing of concrete, mortar or cement; and burning, cutting, grinding and welding on metal or painted surfaces. Compliance with the proposed standards would protect construction employees from excess exposure to many substances, including lead, petroleum distillates, ethylene glycol, xylene, toluene, butoxyethanol, hexylene glycol, mercury compounds, titanium dioxide, cement dust, and silica.

In the maritime industry lower exposure levels should benefit employees engaged in welding, painting, and bulk cargo handling exposed to metal fumes, solvents, and various dusts. Tank cleaning operations also involve potential exposures to many of the chemicals in the proposed regulation.

In the agriculture industry, employee exposures above the proposed PELs occur during silo operations, grain handling, cotton ginning, and grape harvesting. These operations can involve exposures to grain dust, cotton dust, nuisance dust, or silica.

In general industry, compliance with the proposed regulation would result in lower occupational exposures to asphalt, fibrous glass, RCF, and mineral wool. Employees are exposed to these substances during the production of asphalt and vitreous fibers and during the use or manufacture of products containing these substances.

OSHA estimates that full compliance with the proposed standard across all affected industries would potentially prevent about 8 to 13 fatalities and about 31,000 illnesses (including about 12,000 illnesses involving lost workdays) annually. The primary impact would be in the construction industry, with approximately 7 to 11 fatalities and 21,600 illnesses (including 10,200 illnesses involving lost workdays) potentially prevented each year. In the maritime industry, an estimated 1 to 2 fatalities and 200 illnesses would be avoided each year (including 60 illnesses involving lost workdays); in agriculture full compliance may prevent about 9,000 illnesses annually (including 2,000 illnesses involving lost workdays); and in general industry less than one fatality and about 500 illnesses (including 100 illnesses involving lost workdays) would be avoided annually.

Technological Feasibility and Costs of Compliance

The proposed standard requires employees to be protected against overexposure to regulated substances. The estimated costs of compliance for the proposed rule reflect the incremental costs necessary to reduce exposure levels below the proposed PELs for all employees.

The activity-based approach used to determine exposures and the need for additional controls in construction allowed for explicit consideration of mixed exposures. Exposures to multiple substances were evaluated according to the formula in the proposed regulation; combined exposures exceeding unity were considered to be exposures above the proposed PELs. As a result, the costing methodology included allowances for meeting the mixed exposure limit (MEL) as well as individual PELs.

In many activities engineering controls and work practices will effectively reduce airborne concentrations of hazardous substances. These may include fans, fresh air supply blowers, portable exhaust hoods, enclosures, equipment-mounted dust catchers, vacuum cleaning, and water spraying. In activities for which feasible engineering controls are unavailable or insufficient, respiratory protection would be required. An evaluation of the activities potentially affected by this rulemaking has established that compliance with the proposed regulation can be achieved in all industries through an appropriate combination of engineering controls, work practices, and respiratory protection.

The total estimated annual costs of achieving full compliance with the proposed standard in all industries with the proposed PEL of 5 mg/m³ for asphalt fume is approximately \$103 million. The

annual cost for the construction industry would be about \$94 million, the annual cost for the maritime industry would be about \$5.7 million, the annual cost for the agriculture industry would be about \$2.7 million, and the annual cost for general industry would be about \$0.6 million.

With a PEL for asphalt fume of 0.2 mg/m³ the total cost would be approximately \$163 million. Compliance costs for the construction industry would be about \$51 million higher, and compliance costs in general industry would be about \$9 million higher.

In the construction industry, the highest costs are associated with painting, welding, and paint removal, which are concentrated in SIC 1721 (Painting and Paper Hanging), and 1799 (Special Trade Contractors, Not Elsewhere Classified). Respiratory protection accounts for the largest share of compliance costs at \$54 million with an asphalt PEL of 5 mg/m³.

In the maritime industry, most of the compliance costs are associated with painting and welding activities in the shipbuilding and repair industry. In the agriculture industry, the estimated costs of compliance are concentrated in the cotton ginning sector. In general industry the compliance costs are primarily attributable to the proposed PELs for fibers.

Economic Impacts

The costs associated with compliance with the proposed standard would represent less than 0.1 percent of the revenues of the affected industries. The proposed PELs generally would not require drastic or widespread changes. Many employers who currently utilize sound industrial hygiene practices in activities with potential exposures would already be in compliance with the proposed standard.

The overall impact of compliance with the proposed requirements would be an increase in efforts to control employee exposures during activities with recognized potential hazards. The costs would generally be incurred on a per employee basis and on average would represent an increase of less than 0.1 percent of labor costs. These costs should be bearable for all firms and would not create any significant competitive disadvantage for small establishments.

Economic impacts in the maritime and agriculture industries are expected to be minimal. The extent of exposures and necessary control measures would be limited, and the costs of compliance would not represent a substantial burden. In general industry some

th

additional costs for employee protection would have to be incurred during the production and use of vitreous fibers. The proposed PELs for fibers and for asphalt fume are not expected to produce any significant negative impacts.

B. Preliminary Regulatory Impact Analysis for Construction

1. Summary

This section examines the technological feasibility, costs, benefits, and economic impacts associated with this rulemaking for the construction industry. In addition, an industry profile and an evaluation of nonregulatory alternatives is provided. This chapter is divided into seven parts. Part 1, this summary, briefly introduces the other six parts.

Part 2 provides descriptive statistics about the construction industry and each of its subindustries. The industry employs 5 million workers who construct a wide variety of projects including housing, industrial buildings, roads, and power plants. Each project may employ a combination of contractors and subcontractors that specialize in tasks such as carpentry,

painting, or roofing.

Part 3 describes the extent of worker exposures to the substances considered in this rulemaking. Exposures to solvents used in paints and adhesives occur during painting activities, floor work operations, and during the application of single-ply membrane roofing systems. Exposures to lead and other metals can occur when working on painted surfaces, and when welding or soldering. Silica and other particulates may be present during any dusty operation such as abrasive blasting, cement mixing, or earthmoving. Paving and roofing work involve exposures to asphalt fumes. Dozens of other activities, causing significant exposures to over 80 different substances, have been identified.

Virtually all 5 million workers in the construction industry are potentially exposed to one or more of the substances in this proposed rule. Exposures may be intermittent, infrequent, and below the proposed limits, but potential overexposures are not uncommon. OSHA estimates that eliminating all worker exposures above the proposed PELs would result in the prevention of an estimated 7-11 fatalities, 10,200 illnesses involving 214,000 lost workdays, and 11,400 nonlost workday illnesses annually.

Part 4 discusses alternatives to this rulemaking and provides the basis for the conclusion that this proposed

regulation is necessary and costeffective.

Part 5 describes specific activities involving exposures and determines the technological feasibility of meeting the proposed PELs. Engineering controls are available to reduce some exposures but these are not always applicable for all activities. As currently practiced in the construction industry, respiratory protection may be needed to achieve compliance in some high exposure situations. Compliance with the proposed PELs would require an increase in respirator usage but the overall utilization rate would remain relatively low. With an alternative PEL of 0.2 mg/m3 for asphalt fume, a significant increase in respirator use would be necessary for asphalt roofing and paving operations.

Part 6 presents the estimated costs of compliance. Total annualized compliance costs would be about \$94 million with a PEL for asphalt of 5 mg/ m3. The highest costs are associated with painting and welding, which are concentrated in SIC 1721 (Painting and Paper Hanging) and SIC 1799 (Special Trade Contractors, Not Elsewhere Classified). The majority of the compliance costs by type of control is for respiratory protection at \$54 million. A PEL of 0.2 mg/m3 for asphalt would increase total estimated compliance costs by about \$51 million, primarily for respiratory protection during asphalt

roofing and paving work.

Part 7 assesses the economic impacts of the proposed rule. Costs of compliance are small compared to average revenues for all SIC groups. Overall demand for construction is not expected to be affected because the increased cost of projects would be minimal. Slight cost increases may result for some painting and other activities as the added cost of worker protection is included in the cost of completing the work. The rule would apply to all work done within the United States, and thus international competitiveness would not be directly affected.

2. Industry Profile

Overview. The construction industry is covered by three two-digit Standard Industrial Classification (SIC) codes: SIC 15, Building Construction, General Contractors; SIC 16, Heavy Construction Except Buildings, General Contractors; and SIC 17, Special Trade Contractors. The term construction includes new work, additions, alterations, reconstruction, installations, and

Special trade contractors are primarily engaged in specialized construction activities, such as

plumbing, painting, and electrical work. and work for general contractors under subcontract or directly for property owners. General contractors usually assume responsibility for an entire construction project, but may subcontract to others all of the actual construction work or those portions of the project that require special skills or equipment. General contractors thus may or may not have construction workers on their payroll.

The most recent detailed data on the construction industry are found in the 1987 Census of Construction Industries, issued by the U.S. Department of Commerce in March, 1990. During 1987, establishments with paid employees accounted for \$500 billion in total value of construction business. Their payments for construction work subcontracted to others amounted to \$132 billion, leaving a net value of construction work of \$368 billion. In addition, these establishments paid out \$138 billion for the cost of materials. fuels, power, rental of equipment and buildings, and other purchased services. Value added for the construction industry in 1987 was estimated to be \$230 billion.

In 1987 there were approximately 540,000 establishments in the construction industry employing a total of over 5 million people. According to the Census of Construction, the total payroll for the construction industry in 1987 was \$111 billion. The total hours worked by construction workers during the year were estimated to be 6.7 billion

Residential Building Construction. Residential building construction accounts for over 30 percent of the total value of construction [1]. This category includes SIC 1521, General Building Contractors-Single-Family Houses; SIC 1522, General Building Contractors-Other Than Single-Family; and SIC 1531. Operative Builders. Operative builders are primarily engaged in the construction of single-family houses and other buildings for sale on their own account rather than as contractors.

The residential building construction industry has experienced tremendous growth over the past decade. This is partly due to the substantial decline in mortgage rates since the early 1980s, from a high of 15.14% in 1982 to a low of 9.29% in 1988 [2]. Because of high real interest rates from 1979 to 1982, there was substantial pent-up demand for housing when interest rates began to fall (making the cost of housing more affordable).

The increase in the nominal price of housing due to high inflation rates at the

beginning of the 1980s helped many second-time home buyers, who were able to take advantage of increased equity available in their homes. The Department of Commerce estimates that the cost of construction index (1982 = 100) rose from 63.6 in 1977 to 102.6 in 1983. The first-time home buyer was helped by the decline in interest rates, but hurt by the increase in home prices over this same period. The average sales prices of new homes sold in the United States increased from \$89,800 in 1983 to \$138,200 in 1988, an increase of 53.9 percent [2]. The improved performance of the economy during this time period led to an increase in residential building activity, due to the increase in real personal income that occurred over this time period, from \$9,725 per capita in 1982 to \$11,012 per capita in 1987 [3].

However, in 1989, private residential construction decreased by about one percent in constant dollar value. Housing starts fell six percent, from 1.49 million units in 1988 to 1.40 million units in 1989, with declines both in single- and multi-unit structures. While interest rates increased during the first part of 1989, continuing a trend established in 1988, by mid-year of 1989, mortgage rates declined to near 10 percent during the third quarter where they remained through the end of 1989. Mortgage interest rates averaged 10.3 percent during 1989.

Rising interest rates in early 1989 kept new home sales 6.4 percent below 1988 levels, although the sales volume of existing homes increased slightly. Between 1982 and 1989, median new home prices rose 81 percent, while disposable income per capita (in current dollars) increased by about 50 percent. While the decline in interest rates offset rising home prices between 1983 and 1987, both housing prices and interest rates rose in 1988 and early 1989 [4]. As of August 1990, home sales were 10 percent below their level of the previous

An area that is likely to grow within the residential building industry is the residential remodeling market. Most home builders that have added remodeling to their line of services have done so because remodeling is less cyclical than new building construction. Last year the top five remodeling markets were Los Angeles/Long Beach, followed by Washington, D.C., New York, Chicago, and San Francisco. From 1984 to 1987, total residential improvements increased by 37.1 percent [5]. However, in 1989, home owners only spent 1.3 percent more than the previous year for upkeep and improvement of residential properties compared to the 7.7 percent increase in 1988. The slower growth in 1989 reflected the country's slower economic growth, higher interest rates, and weaker consumer confidence levels [4].

Residential construction also includes spending for hotels and motels, which represented about \$9 billion of the total value of construction in 1987 [1]. It is generally believed that the hotel market has become somewhat overbuilt in the 1980s, and that further construction will occur at a slower pace until some of the excess capacity is absorbed [6]. A new trend in the hotel construction market is a move toward specialization in order to capture a certain market sector, such as business travelers. This may provide for some new hotel construction in certain geographic locations [7].

In 1989, construction of hotels and motels increased substantially over prior years, reflecting an international hotel-building boom. That boom has probably peaked in the United States and a 10 percent decline is likely in 1990 and continuing in 1991 [4].

According to the Census of Construction [1], there were almost 120,000 establishments classified as general contractors or operative builders in residential building construction in 1987. They employed over 600,000 workers and accounted for over \$100 billion of the total value of construction work. These figures do not include residential construction work done by special trade contractors. Statistics for each of the 4-digit residential construction SIC codes are presented in Table V-B1.

Non-Residential Building Construction. The non-residential building industry is divided into two sectors: Industrial buildings and warehouses (SIC 1541) and nonresidential buildings, other than industrial buildings and warehouses (SIC 1542). SIC 1541 is primarily made up of manufacturing facilities and

warehouses. SIC 1542 consists primarily of commercial, recreational, hospital, religious, and office buildings.

The non-residential building construction industry is dependent upon the economic environment in which it operates. Factors such as interest rates. manufacturing productivity, currency exchange rates, capital expenditures,

labor costs, and the stock market all influence the market for non-residential building construction.

The demand for manufacturing facilities in the future will depend upon the trading position of the United States in manufactured goods. If the manufacturing sector in the United States continues to expand, the demand

General Contractors—Single Family Houses
 General Contractors—Residential Buildings Other Than Single-Family.

⁴ Excludes value of work subcontracted.

for new manufacturing facilities (by both domestic and foreign producers) should increase significantly. This increased demand could occur because of one or all of the following reasons: High levels of capacity utilization, increased exports due to the fall in the value of the dollar relative to Japanese and European currencies, and relatively high labor costs overseas. Capacity utilization figures for the manufacturing industry have increased dramatically since 1982, from 70.3 percent in 1982 to 81.1 percent in 1987 [3]; industry experts generally consider 85 to 90 percent to be the viable maximum.

Value of industrial construction increased more than five percent in 1989 in constant dollar value. Further increases in industrial construction are expected because many of the manufacturing industries are operating at a high capacity-utilization rate.

International competition has been constraining the need for United States industries to construct new plants in the past but if the trade deficit continues to be reduced by strong United States exports, industrial construction would benefit from the increased demand. Although the long-term outlook for industrial construction is subject to many uncertainties, it is likely to be one of the stronger construction markets during the next five years [4].

New spending for office building construction has declined every year since 1985, when it reached a high of \$31.6 billion. In 1988, office building construction spending was \$27.4 billion. Construction of office space is heavily dependent upon the growth and structure of employment. Recently, there has been a decline in employment growth for large corporations (greater than 500 employees) but an increase in employment growth for small firms (less than 100 employees). This change in the structure of employment is likely to have a slight positive effect on spending for office buildings, especially in suburban areas [6].

Overall, new office construction continued to decline in 1989 and 1990 and further declines are expected over the next years due to higher vacancy rates and the elimination of many of the tax benefits of commercial buildings. Demand for office construction in the future will be heavily influenced by the need to absorb vacant office space and the need to raise rents to profitable levels. Other important demand factors will be long-run investment in real estate by pension funds and foreign interests [4].

The commercial building sector primarily includes retail shopping, restaurants, and other retail ventures. During the 1980s, retail construction

spending increased by 4.0 percent annually. This rate of growth (much lower than spending growth for offices or hotels) permitted modest expansion without overbuilding in the retail sector. Retail construction is dependent on the housing market which was strong in the 1980s, increasing demand for retail space. Generally, the demand for retail space will lag a change in the housing market by six months to two years.

The relative value of commercial buildings such as shopping centers, warehouses, parking garages, banks, and restaurants declined in 1989 and 1990. The primary causes for the decline are, as in other sectors, overcapacity and the effects of a general decline in the growth rate of the economy. However, the overbuilding problem is not as serious for stores and shopping centers as it is for office buildings and hotels [4].

The commercial building renovation market is expanding as commercial owners face an oversupply of new buildings and industrial owners rein in outlays for new plants. Governments are also renovating an abundance of deteriorating facilities. There has been a steady rise in renovation work over the past two decades. In 1970, contracts for additions and renovations made up only about 16 percent of the non-residential building market but had climbed to 22 percent by 1980 and to 28 percent by 1988. Also, the trend by industrial owners to put the largest share of their capital spending into renovation has intensified in recent years. Today, some of the largest renovation projects can be found in industrial processes and in petroleum refinery markets [8].

General contractors in non-residential building construction (SIC 1541 and SIC 1542) included over 38,000 establishments in 1987. These establishments employed over 600,000 workers. Non-residential construction work done by special trade contractors is not included in these figures. Mean establishment size in SIC 1541 was 20 employees per firm and 16 employees per firm in SIC 1542. Table V-B2 provides a summary of statistics for each nonresidential building construction SIC code.

Total value of non-residential building business done in 1987 was \$111 billion, an increase of 58 percent from the 1982 figure of \$71 billion. Ownership of these projects was divided between the federal government (\$7 billion), state and local governments (\$15 billion), and private owners (\$89 billion). The five largest sectors within non-residential building construction were the following: office buildings-\$28 billion; industrial buildings-\$23 billion; other commercial buildings-\$22 billion;

hospital buildings-\$10 billion; and educational buildings-\$8 billion. Net value of construction work for SIC 1541 and SIC 1542 combined was over \$50 billion in 1987.

Highway and street construction, except elevated highways. Highway and street construction (SIC 1611) has been a large, steady component of public construction expenditures in the 1980s. While state and local government spending on transportation systems has increased steadily throughout this decade, federal government spending has decreased slightly. Because the majority of public spending expenditures on highway and street construction come from state and local governments, the outlook for this industry sector is dependent upon the budgetary future of state and local governments.

Several states that previously have had large resources to commit to new highway projects are no longer able to sustain this level of spending because of budgetary difficulties. The state of Florida, which has spent large amounts on such infrastructure development in the past, is facing severe cash shortages in the Department of Transportation [6]. This has led to a substantial decline in highway and street construction spending. Other states, such as Texas and Massachusetts, are facing similar

situations due to a decline in tax revenues and high debt payments. The decline in highway and street spending by these states has been offset by increased spending by several states such as North Carolina, Kansas, and

California [9].

Table V-B3 shows a summary of statistics for highway and street construction in the United States. In 1987, there were approximately 11,000 establishments in the highway and street construction business (excluding special trade contractors in SIC 17) with 284,000 employees, of whom approximately 239,000 were construction workers. Mean establishment size was 26 workers per firm that year. The value of construction business done in this industry was over \$34 billion in 1987, an increase of over \$14 billion from 1982.

Highway and Street Construction, Except Elevated Highways.

² Excludes value of work subcontracted. Source: Office of Regulatory Analysis, OSHA, U.S. Department of Labor, based on 1987 Census of Construction, U.S. Department of Commerce, March

Heavy Construction, Except Highway and Street Construction. This industry category consists of three subcategories: Bridge, Tunnel and Elevated Highway Construction (SIC 1622); Water, Sewer, Pipeline, Communications and Power Line Construction (SIC 1623); and Heavy Construction, Not Elsewhere Classified (SIC 1629).

New construction of bridges, tunnels and elevated highways is highly dependent upon the amount of funding available from state and local government sources. A large percentage of spending on roads and bridges is for maintenance of current infrastructure, an area in which there may be less freedom to decrease spending due to safety concerns. For the first nine months of 1989, total contract awards for bridges and tunnels were \$4.5 billion, an increase of 11.0 percent over the first nine months of 1988 [6].

In 1989, 25 percent of value of highway construction consisted of work completed on bridges, overpasses, and tunnels; the other 75 percent consisted of flat work. Bridge work is expected to grow faster than flat work during the next several years because of the need to replace obsolete or unsafe bridges. According to the Federal Highway Administration, 23 percent of the highway bridges in the U.S. in 1989 were structurally deficient and an additional 21 percent were functionally or

structurally obsolete.

In 1989, the cost for maintenance and repair work was \$22 billion versus \$29 billion for new highway construction. While some of the maintenance costs were for routine maintenance such as mowing grass, the largest fraction was spent on repaying roads and repainting bridges [6]. In 1983, there were 259,950 bridges in the Federal-aided highway system and 313,700 in the non-Federalaided system.

In early 1990, Democratic and Republican leaders of the House of Representatives' Public Works and Transportation Committee began a review of U.S. infrastructure needs in order to develop legislation "to rebuild America." As the country plans for and pursues the huge job of upgrading the infrastructure, an increasing percent of

expenditures dedicated to

reconstruction, repair and maintenance, especially of bridges, can be expected.

Construction of water, sewer, and power lines (SIC 1623) reflects the expansion of the population and of residential areas. As residential construction increased in the 1980s, construction of these basic services accompanied the new developments. Work in this industry is also dependent on the regulatory atmosphere regarding communication, power, and gas lines. New projects continue to be initiated as demands for water, energy and communications links continues to grow.

SIC 1629 (Heavy Construction, Not Elsewhere Classified) includes activities such as athletic field construction, brush clearing or cutting, dam construction. flood control project construction, land reclamation, marine construction. railroad construction, subway construction, and waste disposal plant construction. Because of the varied nature of these activities, it is difficult to predict the outlook for this industry sector. The overall performance should continue to reflect the general level of activity in the economy as a whole.

Table V-B4 presents summary data about heavy construction, except highway and street construction (SICs 1622, 1623, and 1629). As of 1987, there were approximately 26,000 establishments in these industries, an increase of 8,000 establishments since 1982. The establishments employed approximately 543,000 workers, of whom 444,000 were construction workers. Mean establishment size was 21 employees per firm.

Total value of construction business done in this category in 1987 was over \$48 billion. The five largest categories in the heavy construction industry are the following: sewers and water mains-\$9.6 billion; bridges and tunnels—\$5 billion; blast furnaces-\$4.1 billion; sewage treatment plants—\$3.5 billion; and power and communication lines-\$3.7 billion. The net value of construction work for SIC 1622, SIC 1623, and SIC 1629 was over \$40 billion in 1987.

Special Trade Contractors. Establishments in SIC 17 usually specialize in a specific type of construction work, often based on a specific trade. Special trade contractors may work directly for an owner of a project or may work under subcontract to a general contractor, depending on the type of contracting system used. Work is generally performed at the site of construction, but some special trade contractors may also have shops where they perform work incidental to the job site.

The traditional and most common project delivery system in the construction industry is the general contracting system. Under this system the owner of a construction project, who might be an individual, a private corporation, or a government agency, awards the contract to build the project to a general contractor, also commonly called a prime contractor.

The general contractor's prime function is to assemble the specialty contractors and suppliers needed to construct the project according to the plans and specifications. While a general contractor often performs some of the work on the project with his own employees, much of the work may be performed by subcontractors because the prime contractor might not have the expertise, equipment or the trained work force to perform the work. Some of the work may also be subcontracted in order to reduce the general contractor's

Regardless of how much or how little of the construction work is subcontracted, the prime contractor has the responsibility for coordinating, scheduling, and monitoring all of the work done on the construction site. Thus, the subcontractors are dependent both on the general contractor and the owner of the project for the approval of their work.

Tables V-B5 through V-B7 provide summary statistics on each of the special trade contractor categories.

General divisions of special trade contractor activities include: Plumbing, heating and air conditioning work (SIC 1711); painting and paper hanging (SIC 1721); electrical work (SIC 1731); masonry, stone setting, and other stone work (SIC 1741); plastering, drywall, acoustical, and insulation work (SIC 1742); terrazzo, tile, marble, and mosaic work (SIC 1743); carpentry work (SIC 1751); floor laying and other floor work, not elsewhere classified (SIC 1752); roofing, siding, and sheet metal work (SIC 1761); concrete work (SIC 1771); water well drilling (SIC 1781); structural steel erection (SIC 1791); glass and glazing work (SIC 1793); excavation work (SIC 1794); wrecking and demolition work (SIC 1795); installation or erection of building equipment, not elsewhere classified (SIC 1796); and special trade contractors, not elsewhere classified (SIC 1799).

According to the U.S. Department of Commerce's most recent census of the construction industry, there were approximately 342,000 establishments of special trade contractors (SIC 17) which employed 2.9 million workers in 1987, of whom more than 2.3 million were construction workers. Overall, special trade contractors did over \$200 billion in total business volume and net value of construction work was over \$185 billion. A discussion of special trade contractors by individual four-digit SIC follows

Plumbing, Heating, and Air Conditioning. Table V-B5 summarizes market structure and trends of SIC 171 through SIC 174. Industry sector SIC 1711 consists of plumbing, heating, and air conditioning contractors.

The optimistic contracting picture many mechanical contractors in SIC 1711 enjoyed in 1989 changed rapidly because of the major slowdown in

commercial building. However, jobs like retooling old plants and building efficient ones to help manufacturers lower costs and compete better have shown modest gains. For the 179 firms responding to a 1990 survey of mechanical contractors by Engineering News Record (ENR), 39 percent of new contracts were for the commercial building market, 30 percent for industrial or power markets, 19 percent for the institutional market, and 16 percent for the renovation market. The remainder of revenues came from the water and sewer markets (7 percent), transportation and residential markets (each 2 percent), and other markets (1 percent). Energy-related mechanical work has good prospects because of the crisis in the Middle East, with much of the new work involving alternative sources of energy [10].

The latest economic census conducted by the U.S. Department of Commerce,

Bureau of the Census, indicates that in 1987 there were approximately 70,000 establishments in plumbing, heating and air conditioning contracting (SIC 1711), which is an increase of over 15,000 firms since 1982. These firms employed more than 600,000 workers of whom 470,000 were construction workers. This industry segment did over \$49 billion in construction business in 1987, up from \$33.5 billion in 1982. Net value of construction work was close to \$45 billion in 1987, \$15 billion more than in 1982 [1].

Painting and Paperhanging. Competition among painting contractors increased during 1989 as a downturn in commercial construction forced some firms to cut prices in order to stay in business. Dun & Bradstreet reported that industry failures were up in 1988, climbing from 303 failed firms in 1987 to 327 in 1988. Most of the larger painting contractors performed commercial (41.9

percent), industrial (28 percent), and institutional (10.8 percent) work in 1989, while many of the small firms performed

residential painting [11].

The painting contractor industry has become increasingly sophisticated and capital costs of equipping each worker for industrial painting can be as high as \$500. Much of these costs go into sandblasting equipment, blast material recovery systems, and equipment needed to create a negative air pressure environment to protect workers or production lines from contamination [6].

As the downturn in the commercial building market continued in 1989, competition increased. Jobs that used to have four or five bidders attracted eight or nine; owners began putting off maintenance painting to save money

[10].

According to the U.S. Department of Commerce industry census, there were close to 30,000 establishments in painting and paperhanging (SIC 1721) in 1987, up from 25,000 in 1982. These firms employed 170,000 workers in 1987, of whom over 145,000 were construction workers. This is an increase of 35,000 workers since 1982. Dollar value of business done in 1987 almost \$8 billion compared to \$4.7 billion in 1982. Net value of construction work was \$7.4 billion in 1987, an increase of \$3 billion since 1982 [1].

Electrical Work. In recent years, mergers and acquisitions have contributed to drastic changes in the electrical industry (SIC 1731). In 1988, 590 electrical contractors dropped from the industry's ranks, up nine percent from 1987 according to Dun & Bradstreet [11]. On the other hand, the most recent industry census shows that the actual number of electrical contracting firms operating in the United States has increased by 25 percent between 1982

and 1987 [1].

In ENR's specialty contractors survey, 179 firms who reported at least some electrical work indicated that only eight percent of their 1989 revenues came from transportation jobs and that the commercial (37 percent) and industrial (32 percent) markets dominated their business. The era of giant electrical contractors may be fading because of legal troubles and declining revenues for some of the market's largest contractors. This has opened the market for new contenders.

The outlook for the early 1990s is a cause for caution however. Slowdowns in military construction, automobile plants, and office buildings are depressing the market; bright spots include transportation and renovation which represented 15 percent of revenues in 1989 [10].

The industry census estimates that in 1987 there were over 49,000 electrical contractors performing electrical work (SIC 1731), up from 39,500 firms in 1982. These contractors employed more than 500,000 workers in 1987, of whom 405,000 were construction workers. Total business done was \$36 billion, up 33 percent from 1982. Net value of construction work was \$34.7 billion in 1987 [11]

Masonry, Stone Setting and Other Stone Work. Of the respondents to the 1990 ENR survey of masonry contractors, 23 firms reported revenues substantial enough to place them on the "Top 600 specialty contractors" list. The downturn in commercial building work may be helping masonry contractors that are specializing in restoration work. The reason is that owners are holding onto what they have. Other leading masonry contractors are side-stepping the downturn in commercial building by tapping markets that tend to favor brick and block building materials, such as hospitals, educational and religious buildings, and other institutional buildings.

The U.S. Department of Commerce industry census estimates that there were over 23,000 establishments engaged in masonry work, stone setting, and other stone work (SIC 1741) in 1987, up from 20,000 in 1982. These establishments employed 169,000 workers in 1987, a 40 percent increase over 1982. More than 150,000 of these workers were construction workers in 1987. Total dollar value of construction business done that year was \$8.7 billion. almost twice as much as in 1982. Net value of construction work in 1987 was \$8.3 billion, approximately \$4 billion more than in 1982 [6].

Plastering, Drywall, Acoustical, and Insulation Work. This industry (SIC 1742) consists primarily of wall and ceiling contractors. Competition is intense in this market because of the relative ease of entry related to low capital requirements. In 1989, business failures among wall and ceiling contractors climbed seven percent with 266 firms going out of business.

In 1989 there was \$697.1 million worth of work performed by the top 20 wall and ceiling contractors. This was a 34 percent increase over 1988 work according to ENR's 1990 survey. In 1989, the commercial building market accounted for 70 percent of the revenues, followed by the institutional market at 14 percent and the residential market at 7 percent. Only 11 percent of the top 20 firms' business came from renovation work. However, most wall and ceiling contractors expect repair and remodeling work to surpass new

construction contracts in the near future

According to the U.S. Department of Commerce's Bureau of the Census, there were about 18,000 wall/ceiling contractors (SIC 1742) in 1987, up from 16,000 in 1982. These establishments employed over 250,000 workers in 1987 (an increase of 50,000 over 1982), of whom 217,000 were construction workers. Total dollar value of business done that year was over \$16 billion, \$6 billion more than in 1982. Net value of construction work increased by \$6 billion, from \$9 billion in 1982 to \$15 billion in 1989 [1].

Terrazzo, Tile, Marble, and Mosaic Work. The U.S. Department of Commerce census estimates that there were 5,000 establishments engaged in terrazzo, tile, marble and mosaic work (SIC 1743) in 1987, an increase of more than one thousand firms since 1982. These establishments employed 34,000 workers in 1987, of whom 28,000 were construction workers. Total dollar value of business done exceeded \$2 billion, up from \$1 billion in 1982. Net value of construction work in 1987 was also approximately \$2 billion [1].

Carpentry Work. Table V-B6 summarizes market structure of special trade contractors in SICs 1751 through 1781. The most recent census by the U.S. Department of Commerce estimates that there were 36,000 firms engaged in carpentry work (SIC 1751), an increase of more than 5,000 over 1982. These establishments employed 190,000 workers in 1987, of whom 164,000 were construction workers. Dollar value of business done in 1987 was \$11 billion, approximately twice as much as in 1982. Total net value of construction work was \$10 billion in 1987, up from \$4.8 billion in 1982.

Carpentry is one of the major specialty trades in construction. Wood is a preferred and common building material with many applications and its use almost always requires the skill of a carpenter. Over 60 percent of the total value of construction work by carpenters is in residential building construction, reflecting the predominant use of wood in these buildings. About 45 percent of carpentry work is for detached single-family houses, where carpenters are often responsible for completing the whole structure. Carpentry is essential in other construction projects as well; for example, carpenters may construct concrete forms and build platforms and guardrails.

Many workers in the carpentry trade act as independent contractors and may only work part of the year. Thus, the number of full-time equivalent carpenters employed by establishments (as reported by the Department of Commerce) may significantly underestimate the number of people classifying themselves as carpenters. Based on household data from the Bureau of Labor Statistics Employment and Earnings series, there were an estimated 1.3 million carpenters in the United States in 1989.

Floor Laying and Other Floor Work, NEC. In 1987, there were over 8,000 establishments engaged in floor laying and other floor work (SIC 1752) according to the U.S. Department of Commerce census estimates. This was an increase of approximately 2,000 firms over 1982. These firms employed close to 45,000 workers in 1987, of which more than 34,000 were construction workers. Dollar value of business done rose to \$3.7 billion that year, up from \$1.9 billion in 1982. Net value of construction work increased by \$2 billion during that same period to \$3.4 billion.

Roofing, Siding and Sheet Metal Work. Roofing contractors (SIC 1761) are not likely to suffer from construction cyclicality as much as other trades because a substantial part of their market consists of repair and renovation work. Renovation work for five of the top roofing firms represented 75 percent of their business. The National Roofing Contractors Association conducted a survey of roofers which showed that commercial work, particularly renovation, has grown substantially in

recent years [11].

The 39 largest roofing firms had \$608 million in revenues in 1989, seven percent below 1988. Declines in revenues will have the greatest impact among smaller contractors where competition is the most pronounced. In the single ply roofing market, profit margins are about one percent according to industry sources [6]. In contrast, business for sheet metal firms actually improved in 1989 because rising backlogs from the year before were translated into revenues.

According to the U.S. Department of Commerce, Bureau of the Census, there were an estimated 26,000 establishments in roofing, siding and sheet metal work (SIC 1761) in 1987 which employed 230,000 workers, of whom approximately 187,000 were construction workers. Total dollar value of business done in 1987 was \$15 billion and net value of construction work was \$14 billion.

Concrete work. Concrete contracting (SIC 1771) is a very competitive business consisting of over 23,000 establishments according to the U.S. Department of Commerce. In such a market, a firm with

\$3 million per year in revenues is considered big. The two top ranking concrete contractors have revenues of over \$100 million each. There has been a growing demand for super-flat industrial floors and much of the revenues of the larger firms come from commercial and industrial work; the remainder consists of residential construction and nonbuilding construction. Also, many of the larger firms offer a "turnkey" service that provides for all the concrete needs of a project.

In 1989, some of the big concrete contractors posted gains in revenues, but market prospects softened in 1990 with the hardest hit firms specializing in commercial building. In other subsectors, high rise and automotive markets were down but food processing and retail work were relatively strong as were prospects for paving work [6].

The Bureau of the Census estimates that the concrete contractor industry (SIC 1711) employed 218,000 workers in 1987, of whom 187,000 were construction workers compared to 157,000 and 138,000 respectively in 1982. In 1987, the industry's total dollar value of business done was \$15 billion, up from \$8 billion in 1982. Net value of construction work in 1987 was estimated at \$14 billion compared to \$7 billion in 1982.

Water Well Drilling. There has been little change in the water well drilling industry (SIC 1781) over the past five years. According to U.S. Department of Commerce census estimates, there were 3,400 firms engaged in water well drilling in 1987, 100 establishments fewer than in 1982. These firms employed 18,000 workers in 1987, just one thousand more than in 1982. Of these, 14,000 workers were estimated to be construction workers in 1987. Dollar value of business done in 1987 was \$1.3 billion, only a marginal increase over 1982. Net value of construction work rose from \$1 billion in 1982 to \$1.3 billion in 1987.

Structural Steel Erection. Table V-B7 summarizes market structure and trends of special trade contractors in SIC 179. There have been a number of changes in the steel erection industry (SIC 1791) with a shake out that forced some big companies like Bethlehem Steel Corporation to cease field operations in recent years[6].

To offset revenue losses from the weakening commercial market, the nation's largest steel erection contractors have sought infrastructure work. Just a few years ago the largest firms in the sector found about half their work in the commercial market, with the other half evenly split between the industrial and the bridge and highway markets. By 1990, bridge and highway

jobs accounted for half of total revenue with industrial and commercial jobs splitting the remainder. It is believed that the infrastructure market is strong enough to offset the downturn in the commercial market for most large steel erection contractors. However, erectors that cannot get into the infrastructure market will probably experience economic hardship [6].

The U.S. Department of Commerce estimates that there were 4,000 establishments in the steel erection industry (SIC 1791) in 1987, an increase of 300 firms over 1982. The industry employed 65,000 workers in 1987, up from 62,000 workers in 1982. Of these, 55,000 were construction workers in 1987 and the dollar value of business done that year was \$5 billion, up from \$3.7 billion in 1982. Net value of construction work was \$4.5 billion in 1987, an increase of approximately \$1 billion from 1982.

Glass and Glazing. The United States market for glazing and curtain wall contractors has weakened as the pace of new construction has slowed. In recent years, more than 80 percent of the work of the 25 largest glazing and curtain wall contractors came from the commercial market. According to Dun and Bradstreet, 66 glazing firms failed in 1989 [6]. Many banks have tightened lending to commercial developers. According to industry sources, some banks now expect projects to be 30–50 percent pre-leased before they will consider financing construction [10].

Overall, the U.S. Department of Commerce's 1987 industry census estimates that there were about 5,000 establishments in the glass and glazing contracting industry in 1987 compared to 4,000 in 1982. These establishments employed 41,000 workers in 1987, of whom 29,000 were construction workers. In 1987, total dollar value of construction business done by SIC 1793 was estimated to be \$3.2 billion and net value of construction work was \$3.1 billion compared to \$2.6 billion and \$2.4 billion respectively in 1982.

Excavation Work

There were 6,000 fewer excavation/foundation contractors (SIC 1794) in 1987 than in 1982. This sector has had a particularly large number of failures; even large excavation contractors are having a difficult time maintaining a steady flow of work. There seems to be no particular region of the country that is doing significantly better than the others [6].

Although some of the large general contractors do their own excavation and foundation work, excavation contractors

still dominate the market. Of the \$7.4 billion worth of excavation and foundation work performed in 1987 by specialty contractors, 22.1 percent was for residential construction.

According to the U.S. Department of Commerce industry census, there were 13,400 establishments in 1987 in SIC 1794 compared to 19,600 in 1982. These establishments employed 95,000 workers in 1987, down from 136,000 in 1982. Total dollar value of business done in 1987 (\$8.2 billion) was approximately the same as in 1982. Net value of construction work in 1987 was estimated at \$7.4 billion.

Wrecking and Demolition. Regulation of environmental pollutants, particularly asbestos, has redefined the demolition industry. Those companies who are not gaining experience in asbestos and other hazardous materials are losing market share because developers are looking for demolition firms that can perform the dual function of demolition and abatement.

In 1990, wrecking and demolition firms were squeezed by rising capital requirements, higher insurance costs and stricter environmental regulations. Some smaller demolition contractors were having a difficult time adjusting. However, environmental concerns are creating more work for firms that have the equipment and crews to deal with the more complex environmental cleanus iobs.

In the South, for example, new work is coming from the dismantling of industrial facilities such as petrochemical plants that are environmentally unsound. In the West, infrastructure improvement including freeway work and bridge removal is a major source of work for wrecking contractors. The rest of the country also has a growing need for bridge work over the next several years. Over 40 percent of the country's bridges are in need of rehabilitation or repair. Some of these will be replaced by demolition contractors. High public concern about occupational lead exposure and increased environmental concerns over lead paint abatement should translate into more contracts for firms specializing in removing or working with this heavy metal.

The most recent U.S. Department of Commerce industry census estimates that there were 1,200 firms engaged in wrecking and demolition work (SIC 1795) in 1987, up from 900 firms in 1982. These firms employed over 14,000 workers in 1987, of whom almost 12,000 were construction workers. Dollar value of business done more than doubled from 1982 to 1987, rising from \$400 million to approximately \$910 million,

while net value of construction work changed from \$300 million in 1982 to \$845 million in 1987.

Installation or Erection of Building Equipment, NEC. These special trade contractors (SIC 1796) primarily engage in the installation or erection of building equipment such as elevators, pneumatic tube systems, and dust collecting equipment. Contractors in this industry also install or dismantle machinery or other industrial equipment.

For example, U.S. elevator contractors are part of SIC 1796. United States elevator contractors are coping with fluctuations in the demand for new facilities by capitalizing on a recent trend toward modernization to fend off the effects of a national slowdown in new multi-story construction. The popular trend in upgrading elevators is to replace the conventional relaylodging systems of the 1950s and 1960s with today's state-of-the-art, electronic microprocessor systems, which are easier to install, operate, and maintain. However, in order to install and service such sophisticated equipment, the industry will have to undergo a transformation which will affect its workforce. To improve the workforce. the National Association of Elevator Contractors is spearheading a campaign to better educate field personnel among its existing 400 member companies and to recruit more college and trade school graduates with computer backgrounds into elevator contracting [6].

According to the U.S. Department of Commerce industry census, there were close to 4,000 establishments in SIC 1796, a number which has changed little since 1982. These establishments employed 62,000 workers in 1987, of whom 50,000 were construction workers. Dollar value of business done was estimated at \$5.4 billion, approximately \$1 billion more than in 1982. Net value of construction work was \$5 billion in 1987, up \$1 billion from 1982.

Miscellaneous Special Trade
Contractors, NEC. This industry group
consists of special trade contractors
who are primarily engaged in
construction work and who are not
classified under any of the other
construction industry categories in SIC
1799. This group includes such diverse
firms as swimming pool and fence
construction, erection and installation of
ornamental metal work, house moving,
shoring work, waterproofing, dampproofing, fireproofing, sandblasting, and
steam cleaning of building exteriors.

This group represents almost half (47 percent) of all establishments included in the miscellaneous contractor industry (SIC 179). According to the U.S. Department of Commerce most recent

census figures, there were an estimated 23,000 establishments in SIC 1799 in 1987, 3,000 more firms than in 1982. These establishments employed 176,000 workers in 1987, of whom 140,000 were construction workers. Total dollar value of business done by these firms was \$11 billion in 1987, up from \$6 billion in 1982. Net value of construction work in 1987 was estimated at \$10 billion.

- 3. Employee Exposures and Benefits

Introduction. Employee exposures to the substances included in the scope of this rulemaking are associated with a wide variety of acute and chronic conditions and illnesses. These include sensory irritation, narcosis, systemic toxicity, respiratory disease, neuropathy, and cancer.

Since the adoption of the existing limits twenty years ago, toxicological evidence has become available that shows that adverse health effects can occur as a consequence of exposure to the substances regulated, and that such health effects occur even when exposures are maintained at the current limits. In addition, many substances that have come into widespread use or been introduced since 1970 have been shown to be potentially hazardous in workplace environments. OSHA thus believes that reducing worker exposures

to such substances by lowering existing exposure limits or by adding limits for previously unregulated substances will result in a significantly reduced risk of illness.

This chapter describes both the methodology used to identify construction workers potentially exposed to hazardous substances included in this proposed rulemaking and the expected benefits to those workers resulting from lowering permissible exposure limits.

Data sources and methodology. The extent of exposures to the substances included in this proposed rulemaking for the construction industry was evaluated by first identifying specific activities

with potential exposures.

For each activity, the extent of exposures to the various substances present was determined. Activities involving substances for which OSHA is adding a skin designation were assessed

for dermal exposure.

OSHA used exposure monitoring data from several sources to determine worker exposure levels during construction activities. One source for monitoring data is OSHA's Integrated Management Information System (IMIS) data base. This data base contains exposure measurements obtained by OSHA compliance officers during inspections of worksites. For each site inspected, the IMIS file includes information on the number of employees involved, results of employee air monitoring, and the number of employees potentially exposed to each substance monitored.

Another valuable source of information was the National Institute for Occupational Safety and Health (NIOSH). NIOSH regularly conducts studies on potential occupational health hazards throughout the United States, including the construction industry. NIOSH's health hazard evaluation reports give detailed descriptions of working conditions and activities at a particular site. The chemicals present are identified, recommended controls and work practices are discussed, and exposure monitoring results are analyzed. Although the conclusions in the report concerning possible health hazards are related to a particular site, the data provide a link between a certain set of circumstances and the resulting exposure levels, and can be effectively applied to similar situations for the relevant activity throughout the industry

OSHA collected additional exposure monitoring data specifically for this rulemaking. A series of site visits was conducted by industrial hygienists working for a contractor hired by

OSHA. Establishments were assured of confidentiality, allowed their employees to be monitored, and provided various information such as the duration and frequency of activities, the numbers of employees involved, and the value of the construction work at the project. In return, the establishments received the consulting services of the health professionals for the duration of the visit. Data gathered from this effort served to confirm data from other sources and provided definitive information for principal activities and activities that otherwise would not be as well documented.

OSHA also conducted a major computer-assisted telephone interview (CATI) survey to develop a comprehensive profile of employee exposures in the construction industry. Over 1,100 establishments provided complete responses. The firms were selected at random within 48 survey cells. The survey cells were defined by a combination of SIC code and establishment size. Establishments with fewer than twenty employees were considered small and establishments with twenty or more employees were

considered large.

Each respondent supplied specific information on the demographic characteristics of the firm, the type of construction project covered, and the role of the firm and its employees in the project. Respondents were asked to identify all activities with potential exposures. For each category of construction work, an initial list of activities and associated substances and products served as prompts. The substances and products involved in each of the respondent's activities were then determined and confirmed. In cases where the presence of specific products is easier to identify than the presence of individual chemicals, the names of the products and the manufacturers were solicited and material safety data sheets (MSDSs) were used to identify the relevant chemicals.

The survey requested details about each activity to determine the nature of potential exposures, including information on the work environment, the controls used, the scale of the activity, and the number of workers involved. The data from each respondent were evaluated in combination with documented exposure monitoring results and other research concerning the chemicals present, such as the concentration and quantity involved, the likelihood of becoming airborne, and the stringency of the proposed PEL. The number of workers likely to be exposed and overexposed to various chemicals during each activity

was determined with computer algorithms developed by experienced industrial hygienists using all available data associated with the activity.

The estimates generated from the survey data were derived from the responses of a representative sample of construction establishments within each survey cell. These data were scaled up to national levels through the use of published statistics on total employment by firm size and SIC code. The 1987 Census of Construction Industries, published by the U.S. Department of Commerce in 1990, provides these and other detailed statistics on the construction industry.

Number of Exposed Employees. Table V-B8 presents the total estimated fulltime equivalent number of employees exposed to substances found in the construction industry and considered in this proposed rulemaking. A full-time equivalent exposed employee is comparable to a person-year of exposure, which represents one shift each working day for one year. Due to the nature of some construction activities, the actual number of people who may experience an exposure over the course of a year would be larger. For example, if 100,000 workers were exposed to a chemical for an average of two hours per week, their combined exposure would equal that of 5,000 fulltime equivalent employees.

TABLE V-B8.—EMPLOYEE EXPOSURES TO CHEMICALS IN CONSTRUCTION AD-DRESSED BY THE PROPOSED RULE

-	Chemical		equivalent loyees
Code	Name	Exposed	Exposed above proposed PEL and unpro- tected

Source: Office of Regulatory Analysis, OSHA; based on CONSAD [1].

The total number of employees potentially exposed to one or more substances annually would be over 4 million, the total number of construction workers in the industry. This is due to several factors. Workers in every occupational group in the construction industry engage in one or more of the activities identified as involving exposures to the substances associated with this proposed rule. The workforce in the construction industry is relatively transient and mobile within the industry and workers have a greater likelihood of being assigned to a variety of different tasks over the course of a year. Each firm in the industry may work on several projects with varying activities and exposures. A construction worker engaged in one activity faces potential exposures from other activities occurring in the vicinity.

Substances for which exposures above the proposed PELs are likely to occur most frequently include acetone, butoxyethanol, n-heptane, lead, methyl chloroform, nickel, ethylene glycol, petroleum distillates, portland cement, titanium dioxide, toluene, welding fume, xylene, crystalline silica quartz, and silica cristobalite. Specific chemicals and activities with overexposures are discussed below.

Acetone is a solvent and may be a component in paints and varnishes, rubber adhesives, and vinyl cements. Although this chemical will be present

in many construction activities, most of the overexposures to acetone are expected to occur during the application of single ply membrane roofing systems. Overexposures have also been found during the application of floor coatings and while laying floors, as well as during steel painting and bonding and gluing operations.

N-heptane is a solvent that can be present in many construction applications. Overexposures to n-heptane can occur during the application of single ply membrane roofing systems and during the exterior painting of steel. Through the use of adequate ventilation, exposures can be kept below the PEL and the short-term exposure limit during floor work (patching and resurfacing) and other gluing operations.

Lead exposure is a serious health hazard faced by many construction employees. The risks are compounded because employers may not always be aware of the presence of lead or may underestimate the potential for overexposure. Old lead-based paints may have a lead content of over 30 percent. Severe overexposures can occur when the paint is grinded, burned, or otherwise dispersed into the air. Soldering, brazing, and welding may also involve lead exposures. The proposed PEL for total welding fumes is 100 times the proposed PEL for lead, making specific precautions for lead exposure a necessary consideration when it is present.

Activities where overexposures to lead are most common include abrasive blasting; burning, cutting, or welding on painted steel, welding or cutting galvanized steel; grinding, drilling, chipping, or cutting on any painted surfaces; and soldering or brazing. Over 500,000 construction employees are estimated to be engaged in these activities on a regular basis, which may often be done by inexperienced laborers and helpers.

Potential exposures to lead are expected to become more widespread in the construction industry in the near future. The Department of Housing and Urban Development (HUD) is requiring public housing agencies to inspect housing projects for lead paints by 1994. Abatement is required if lead is present above specified concentrations. The lead abatement industry is expected to grow significantly as the awareness of potential lead hazards increases among all building owners.

A second source of increased exposures to lead will result from increases in infrastructure development efforts. Tens of thousands of bridges, neglected in the past, are in need of

rebuilding, repair, or repainting, and major rehabilitation projects are being initiated or planned throughout the country. The removal of old lead paints and other activities associated with bridge work involve potentially severe exposures even in outdoor settings. Compliance with Environmental Protection Agency (EPA) regulations, which are designed to protect the environment by requiring such operations to be enclosed, further concentrates exposures for workers within the enclosures.

Methyl chloroform is a solvent used in construction activities such as laying floors, surface cleaning and stripping, insulation installation, and other bonding and gluing operations.

Overexposures can be avoided by providing adequate ventilation, but have been found to occur in situations with extended exposures in relatively confined spaces. Surface cleaning and stripping operations are especially prone to result in worker overexposures due to the proximity of the chemical to the breathing zone.

Exposures to airborne concentrations of soluble compounds of nickel are possible during burning, cutting, or welding on painted steel and also during welding or cutting stainless steel.

Ethylene glycol is a component of many latex paints. It can become airborne as either a vapor or a mist during painting operations. When painting is done indoors and concentrations are allowed to build up, overexposures may occur. Workers engaged in interior spray painting for extended periods of time are most likely to experience overexposures.

The presence of petroleum distillates is widespread in the construction industry. It can be a component of such products as laquers, paints, polyester coatings, asphalt products, caulks, sealants, and rubber cements. Often the presence of petroleum distillates will not be a significant hazard, but several activities have been identified where the potential for overexposure exists. These include exterior painting of wood finishes, exterior painting of steel, concrete sealing and coating operations. interior application of floor coatings, interior painting, surface stripping, and preparing concrete forms.

Toluene and xylene are common solvents found in many paints, coatings, caulks, epoxies, adhesives, sealants, and curing agent mixtures. Although most of the construction workforce may be regularly exposed to these agents to some degree, overexposures are relatively limited. Activities with potential for overexposure include the application of single ply membrane

roofing systems, concrete sealing and coating operations, interior application of floor coatings, interior painting, preparing and installing concrete forms, and traffic line painting.

Welding and cutting are common activities that are the main sources of exposure to welding fumes. Overexposures can occur if appropriate

controls are not employed. Based on the CONSAD survey of construction establishments, approximately 10 percent of workers exposed to welding fumes are potentially overexposed.

Exposures to various forms of silica are among the most common exposures to airborne contaminants in the construction industry. Incidences of overexposure are likely to be limited to circumstances involving extended periods of work in dusty environments. These are most likely to occur during earthmoving, trench excavation, abrasive blasting, batch mixing of concrete or mortar, grinding or cutting on concrete and other surfaces, and tunnel blasting and excavation.

Estimated reductions in fatalities and illnesses. The reduction of employee exposures to hazardous substances to a level below that associated with adverse health effects will result in a decrease in the number of fatalities and illness cases among affected construction workers. This section provides estimates of the numbers of fatalities and illnesses that can be expected to be avoided in the construction industry through

compliance with the proposed rule.
As presented in Table V-B8, OSHA has estimated the extent of exposures in the construction industry as the number of full-time equivalent employees exposed. Construction workers performing activities contributing to these exposures are currently at risk of experiencing a variety of adverse health effects brought about by overexposures to the substances included in this rulemaking. Many of these adverse effects, in particular cancer, systemic toxicity, chronic respiratory disease, neuropathy, and chronic liver and kidney damage, can result in lethal outcomes. Employees who are excessively exposed to substances causing organ damage, neurological impairment, or metabolic effects may also be at excess risk of incurring a fatal condition. A description of the risks associated with overexposures to specific chemicals can be found in the health effects section of this preamble.

Table V-B9 presents the extent of exposures above the proposed PELs in construction by substance and type of health effect. Substances for which compliance with the proposed PEL would be equivalent to compliance with existing requirements are not included in this table, and the benefits of compliance with these limits are not attributed to the proposed rule. Such substances include nuisance particulates, limestone, plaster, gypsum, and calcium silicate.

The major health effects category includes respiratory effects, which are primarily due to exposures to silica, soluble nickel compounds, asphalt fume, mica, fibrous glass, and wood dust. Petroleum distillates, lead, n-hexane, and mercury cause neuropathy effects among exposed workers; welding fume, butoxyethanol, and zinc oxide fume are major contributors to systemic toxicity effects; and toluene, methyl chloroform, and n-heptane exposures are associated with narcosis effects. Substances with exposures above the proposed PELs causing increased cancer risk to construction workers include chromic acid and chromates. Sensory irritation results from exposure to ethylene. xylene, hexylene, and propylene; and physical irritation results from exposure to titanium dioxide, portland cement, and molybdenum.

TABLE V-B9.—EXPOSURES IN CONSTRUC-TION ABOVE PROPOSED LIMITS BY TYPE OF HEALTH EFFECT

Type of health effect and substance	Exposures above proposed limits (person- years)
Sensory irritation:	
Ethylene Glycol	7,950
Xylene	4,357

All	121,696

Note: Summation of exposures to different substances may include double counting of employees simultaneously exposed to more than one substance.

Source: Office of Regulatory Analysis, OSHA, U.S. Department of Labor.

OSHA has estimated the expected reductions in illnesses and fatalities resulting from this rulemaking based on full-time equivalent exposures. The PELs are established based on the ability to protect workers from all potential exposure over a full working lifetime, and the risks associated with excess exposure are based on daily full-time exposure for 45 years. Actual total excess risk to construction workers also depends on the overall dose.

As a best estimate of excess risk, it is assumed that the aggregate amount of overexposure will determine the aggregate amount of excess risk, and that this will be a linear (proportional) relationship. There are two offsetting arguments which indicate that the actual total risk for the construction work force

could be higher or lower. If the total risk depends positively on the total number of people exposed as well as on the total amount of exposure, then the actual total risks could be considerably higher. On the other hand, if less frequent exposures result in lower than proportional risk, then the actual risk would be lower than that estimated.

Based on the assumption of proportional risk, and a full-time equivalent population exposed above the proposed PELs continuously over a working lifetime. OSHA estimates that an excess mortality rate in the range of 0.5 to 2 percent (with a best estimate of 1 percent) would result. Fatalities would result from continuous occupational exposure above the proposed PELs for substances associated with cancer and adverse respiratory, narcosis, neuropathy, systemic toxicity, liver, and kidney effects. Substances causing these health effects may also cause other lifethreatening conditions and indirectly contribute to an increased risk of premature death by increasing susceptibility to diseases, weakening immune systems, or through interactions with other chemicals.

Estimates of the extent of exposures above the proposed PELs are classified by type of health effect and presented in Table V-B9. If exposure to each chemical is counted independently, then the estimated total number of personyears of exposure above the relevant proposed PELs is about 90,000 annually. However, total person-years of overexposure may be greater than the number of total full-time equivalent overexposed employees if exposure to more than one substance occurs simultaneously. Since the estimated mortality rate applies to numbers of workers, the number of person-years of overexposure was adjusted downward by 10 percent to account for this possibility. As a result, approximately 81,000 full-time equivalent workers are estimated to be exposed above the proposed PELs with an increased risk of premature death.

Based on the assumption of a 1 percent excess mortality rate among this cohort, an average of 18 fatalities per year would be addressed by this rulemaking. OSHA assumes that reductions in exposures resulting from full compliance with the proposed rule could be expected to prevent about half (7–11) of these fatalities.

OSHA's estimated excess mortality rate is conservative compared with other mortality studies and epidemiological research in the construction industry. An occupational mortality study conducted by the

California Department of Health Services revealed that laborers and other construction workers experience significantly higher mortality rates than the general population [6]. Mortality rates were an average of over 50 percent higher for lung cancer, other cancers, circulatory system diseases, cerebrovascular disease, chronic obstructive pulmonary disease, cirrhosis and other liver disease, and diseases of the urinary system. These data indicate that the excess mortality due to overexposures among construction workers may be far greater than estimated above. However, a portion of this excess mortality may be related to causes other than exposures to substances in this proposed rulemaking (e.g. cigarette smoking).

On the basis of exposure data delineated further in Section V-B-6 (Costs of Compliance), OSHA estimates that about 84,000 full time equivalent construction employees may be exposed to an average of 0.5 mg/m3 asphalt fume. The quantitative risk assessment for asphalt fume presented in this preamble indicates that this exposure may produce approximately 4 to 5 excess fatalities due to lung cancer annually. Although exposures may be reduced for some employees by using applicable engineering controls and work practices (such as insulating pipes and keeping asphalt temperatures low), OSHA expects that 80,000 FTE employees would need respiratory protection in addition to such controls to comply with a PEL of 0.2 mg/m3. According to the results of the quantitative risk assessment, about 3 to 4 fatalities per year may thus be avoided by reducing the average exposure to 0.05 mg/m3.

The number of illnesses associated with overexposures in construction that are potentially preventable by this proposed rulemaking is difficult to assess. The Bureau of Labor Statistics (BLS), in its annual survey of occupational injuries and illnesses in the United States, found that 7,700 illnesses were documented and recorded in the construction industry in 1989 [7]. It is widely recognized that these data significantly underestimate the prevalence of occupational illness because only cases recorded and reported by employers are counted.

In the construction industry it is likely that many occupationally related illnesses are never documented as such. One reason may be that neither the employer nor the employee may be aware that an illness is occupationally related. In addition, chronic and disabling illnesses may only become

apparent after the exposure has ceased, and none of these cases are likely to be included in employer records. Relatively high rates of worker turnover experienced in construction make tracking of exposures more problematical; subsequent employers would probably not be aware of exposures with previous employers. Underreporting of illnesses with latency periods would be greater than the underreporting of illnesses with toxic or acute effects.

In order to compensate for the underreporting of occupationally related illnesses, the BLS estimates were multiplied by a factor of 5. With this adjustment the estimated annual number of illnesses in construction is 38,500.

Some of these illnesses would not be addressed by the proposed standard. Illnesses in construction may include effects associated with exposures to hazardous agents or physical stress, such as radiation, noise, and ergonomic stress. However, illnesses which are covered include skin disorders; the proposed standard adds skin designations for specific substances as appropriate, and costs of providing dermal protection are included in the estimated compliance costs. Although the PELs set by this standard address airborne concentrations, a general reduction in exposure through absorption and ingestion can be expected through increased awareness and improved work and hygiene practices.

The data from the BLS survey indicate that about 30 percent of reported illnesses in construction are due to repeated trauma, physical agents, and poisonings [7]. Overall, 70 percent of the total illnesses in construction, or approximately 27,000 cases, are considered potentially preventable by

the proposed standard.

As compliance with the proposed rule would offer protection from excessive dermal and airborne exposures to hazardous chemicals encountered by construction workers in a comprehensive manner, an 80 percent reduction in the incidence of occupationally related illnesses is projected, with a range of 70 to 90 percent. Thus, OSHA estimates that compliance with the proposed rule would potentially prevent about 21,600 illnesses annually.

BLS reported that about 47 percent of the recorded illnesses involved lost workdays, and that an average of 21 lost workdays resulted from lost workday cases [7]. OSHA assumes these same rates apply to unrecorded illnesses. Compliance with the proposed rule is thus estimated to prevent about 10,200 illnesses involving lost workdays, and reduce the number of lost workdays in construction by about 214,000 workdays.

Based on research by Kip Viscusi, the implicit average value of avoiding each lost workday case would be about \$40,000 [11]. This value is based on a willingness-to-pay methodology and takes existing compensation programs into account. The total potential benefit associated with the prevention of lost workday illnesses alone would be \$408 million.

In addition, excess exposures to some substances in the proposed rule cause material impairments of health that may not always be considered illnesses. Cases of physical and sensory irritation are likely to occur regularly among hundreds of thousands of construction workers. Eliminating these material impairments of health should further reduce the prevalence of illnesses among these workers. Compliance with the proposed PELs would also produce benefits that cannot be quantified, such as the increased comfort and productivity of employees.

OSHA requests comments and data on the prevalence of illnesses and health-related fatalities in construction, as well as on the potential effectiveness of the proposed standard in reducing the incidence of these cases.

4. Nonregulatory Alternatives

Introduction. The declared purpose of the Occupational Safety and Health (OSH) Act of 1970 is "* * * to assure so far as possible every working man and woman in the Nation safe and healthful working conditions and to preserve our human resources. * * *" Thus, the Act requires the Secretary of Labor, when promulgating occupational safety and health standards for toxic materials or harmful physical agents, to set the standard "* * * that most adequately assures, to the extent feasible, on the basis of the best available evidence, that no employee will suffer material impairment of health or functional capacity. * * *" It is on the basis of this congressional directive that OSHA has initiated regulatory actions to reduce the adverse health effects associated with occupational exposure to hazardous substances in the construction industry.

Market imperfections. Economic theory suggests that the need for government regulation is greatly reduced where private markets work efficiently and effectively to allocate health and safety resources. The theory typically assumes perfectly competitive labor markets where workers, having perfect knowledge of job risks and being perfectly mobile among jobs, command wage premiums that fully compensate for any risk of future harm. Thus, theoretically, the costs of occupational injury and illness are borne initially by the firms responsible for the hazardous workplace conditions and ultimately by the consumers who pay for the final goods and services produced by these firms. With all costs internalized, private employers have an incentive to reduce hazards wherever the cost of hazard abatement is less than the total cost to the firm, the workforce, and society of the expected injury or illness. The resultant level of safety and health is considered efficient in the sense that it minimizes the sum of the costs (and foregone benefits) of hazard prevention and of injury or illness.

The conditions of perfect competition do not need to be completely satisfied in order for the forces of the market to approximate an efficient outcome. However, some market imperfections can produce sub-optimal results that can be improved upon with regulatory action. In the case of this rulemaking, employees face a significant risk of material impairment of health which is not adequately addressed by current nonregulatory alternatives. OSHA therefore believes that it must take appropriate actions to provide greater health protection for construction workers exposed to toxic substances.

Evidence indicates that market forces in the construction industry have not been effective in reducing excessive occupational exposure to hazardous substances, thereby contributing to the consequent development of occupational diseases. In spite of the danger associated with the inhalation or other exposure to hazardous substances, the social costs of production have not been internalized, in part because of market imperfections and the existence of externalities. Consequently, the amount of protection that the private market will offer to construction workers differs from the socially desired level.

First, evidence on occupational health hazards in general suggests that in the absence of immediate or clear-cut danger, employees and employers have little incentive to seek or provide information on the potential long-term effects of exposure. Employers faced with potentially high compensatory payments may in fact have a disincentive to provide information to employees. When relevant information is provided, however, employers and employees might still find informed decisionmaking a difficult task, especially where long latency periods precede the development of chronic disabling disease. Moreover, if signs and symptoms are nonspecific-that is, if an illness could be job-related or could have other causes-employees and employers may not link disease with such occupational exposure.

Second, even if workers were fully informed of the health risks associated with exposure to hazardous substances, many face limited employment options. Nontransferability of occupational skills and high national unemployment rates sharply reduce a worker's expectation of obtaining alternative employment quickly or easily.

In many regions of the country, the practical choice for workers is not between a safe job and a better paying but more hazardous position, but simply between employment and

unemployment at the prevailing rates of pay and risk. In addition to the fear of substantial income loss from prolonged periods of unemployment, the high costs of relocation, the reluctance to break family and community ties, and the growth of institutional factors such as pension plans and seniority rights serve to elevate the cost of job transfer. Thus, especially where wages are more responsive to the demands of more mobile workers who tend to be younger and perhaps less aware of job risks, hazard premiums for the average worker will not fully compensate. Where this is the case, labor market negotiations are unlikely to reflect accurately the value that workers place on health.

In addition to these market imperfections, externalities occur if employers and employees settle for an inefficiently low level of protection from hazardous substances. For the competitive market to function efficiently, only workers and their employers should be affected by the level of safety and health provided in market transactions. In the case of occupational safety and health. however, society shares part of the financial burden of occupationally induced diseases, including the costs of premature death, chronic illness, and disability. Those individuals who suffer from occupationally related illnesses are cared for and compensated by society through taxpayer support of social programs, including welfare, Social Security, and Medicare. These combined factors of labor market imperfections and the existence of externalities contribute to the failure of the market to supply sufficiently healthful working conditions where hazardous substances exist in the construction industry.

Tort Liability. The use of liability under tort law is one nonregulatory alternative that has been increasingly used in litigation concerning occupationally related illnesses. Prosser [1] describes a tort, in part, as a "civil wrong, other than a breach of contract, for which the court will provide a remedy in the form of an action for damages," although he says that "a really satisfactory definition has yet to be found."

If the tort system applies, it would allow a worker whose health has been adversely affected by occupational exposure to a hazardous substance to sue and recover damages from the employer. Thus, if the tort system is effectively applied, it might shift the liability of direct costs of occupational disease from the worker to the firm under certain specific circumstances.

With very limited exceptions, however, the tort system is not a viable

alternative in dealings between employees and employers. All states have legislation providing that Workers' Compensation is either the exclusive or principal remedy available to employees against their employers. Thus, under tort law, workers with an occupational disease caused by exposure to a hazardous substance can only file a product liability suit against a third party manufacturer, processor, distributor, sales firm, or contractor. It is often difficult, however, to demonstrate a direct link between an exposure to a hazardous substance and the illness.

In order to pursue litigation successfully, there must be specific knowledge of the magnitude and duration of a worker's exposure to a hazardous substance, as well as the causal link between the disease and the occupational exposure. Usually, it is extremely difficult to isolate the role of occupational exposures in causing the disease, especially if workers are exposed to many toxic substances. This difficulty is further compounded by the long latency periods that are frequently involved. In addition, the liable party must be identifiable, but workers may have several employers over a working lifetime. The burden of proof that an occupational exposure to a hazardous substance occurred, that a specific employer is the liable party, and that the exposure level was significant may prohibit the individual from initiating

The costs associated with producing information and with litigation itself may be quite substantial. First, information is a public good, which means that once it is produced, it is available for all. As a result, public goods are typically underproduced relative to what is considered economically efficient. This general undersupply of information adversely affects workers' awareness of the cause of their illnesses and thus reduces the likelihood that they will pursue tort liability suits.

Second, information is not a costless commodity. The time and money required to obtain, research, and distribute information can be substantial. Since the outcomes of liability cases are frequently uncertain, additional information is almost always preferable. The complexity of the subject matter, for health standards in particular, requires a large amount of information as a starting point for a lawsuit. These costs would have to be borne by potential plaintiffs before the lawsuit is initiated.

Third, legal proceedings impose costs on both plaintiffs and defendants. In

deciding whether to sue, the tort victim must be sure that the size of the claim will be large enough to cover legal expenses. In effect, the plaintiff is likely to face substantial transaction costs in the form of a contingency fee, commonly 33 percent, plus additional legal expenses. The accused firm must also

pay for its defense.

The majority of occupational disease tort activities has involved workers exposed to asbestos. To date, over 100,000 individual plaintiffs have filed asbestos lawsuits in the country. These employees avoided the exclusive remedy of Workers' Compensation by suing suppliers of asbestos instead of employers. A report prepared by the Research Triangle Institute [2] contains some data pertaining to legal costs and the size of awards associated with tort law. One investigator, for example, found that an average ratio of legal costs to proceeds was 37 percent for a sample of cases. The high costs and uncertainties associated with tort law make it an inefficient mechanism for ensuring adequate protection of workers' health.

Insurance and liability costs are not borne in full by the specific employer responsible for the risk involved. For firms that are insured, the premium determination process is such that premiums only partially reflect changes in risk associated with changes in exposure to hazardous substances. This lack of complete adjustment is the socalled "moral hazard" problem, which is the risk that arises from the possible imprudence of the insured. As the insured firm has paid an insurance company to assume some of the risks, that firm has less reason to exercise the diligence necessary to avoid losses. Transfer of risk is a fundamental source of imperfection in markets.

Workers' Compensation. The Workers' Compensation system is a result of the perceived inadequacies in liability or insurance systems to compel employers to prevent occupational disease or compensate workers fully for their losses. The system was designed to internalize some of the social costs of production, but in reality it has fallen short of compensating workers adequately for occupationally related disease. Thus, society shares the burden of occupationally related health effects, premature mortality, excess morbidity, and disability through taxpayer support of social programs such as welfare, Social Security disability payments, and

Compensation tends to be inadequate especially in permanent disability cases, in view of the expiration of benefit entitlements and the failure to adjust

benefits for changes in a worker's expected earnings over time. As of January 1987, eight states restricted permanent disability benefits either by specifying a maximum number of weeks for which benefits could be paid or by imposing a ceiling on dollar payments

At present, time and dollar restrictions on benefit payments are even more prevalent in the area of survivor benefits. The duration of survivor benefits is often restricted to 10 years, and dollar maximums on survivor payments range from \$7,000 to \$60,000. In addition, it should be noted that if the employee dies quickly from the occupational illness and has no dependents, the employer need pay only nominal damages under Workers' Compensation (i.e., a \$1,000 death

benefit).

Finally, in spite of current statutory protection, disability from occupational diseases represents a continuing, complex problem for Workers' Compensation programs. Occupational diseases may take years to develop, and more than one causal agent may be involved in their onset. Consequently, disabilities resulting from occupationally induced illness often are less clearly defined than those from occupationally induced injury. As a result, Workers' Compensation is often a weak remedy in the case of occupational disease. For example, as recently as April 1983, the U.S. Supreme Court refused to hear an occupational disease case (Richard D. Bunker v. National Gypsum Co.) involving a worker who was diagnosed as having asbestosis 23 years after the expiration of the 3 year time limit allowed by Indiana law for filing a compensation claim [4]. Indeed, there is some evidence indicating that the great majority of occupationally induced illnesses are never reported or compensated [5].

The insurance premiums paid by a firm under the Workers' Compensation system are generally not experience rated; that is, they do not reflect the individual firm's job safety and health record. About 80 percent of all firms are ineligible for experience rating because of their small size. Such firms are class rated, and rate reductions are granted only if the experience of the entire class improves. Even when firms have an experience rating, the premiums paid may not accurately reflect the true economic losses. Segregation of loss experience into classes is somewhat arbitrary, and an individual firm may be classified with other firms that have substantially different normal accident rates. An experience rating is generally based on the benefits paid to workers,

not on the firm's safety record. Thus, employers may have a greater incentive to reduce premiums by contesting claims than by initiating safety measures.

In summary, the Workers' Compensation system suffers from several shortcomings that seriously reduce its effectiveness in providing incentives for firms to create safe and healthful workplaces. The scheduled benefits are significantly less than the actual losses to the injured workers, and recovery is often very difficult in the case of occupational diseases. Thus, the existence of a Workers' Compensation system limits an employer's liability significantly below the actual costs of the injury. In addition, premiums for individual firms are unlikely to be specifically related to that firm's risk environment. The firm, therefore, does not receive the proper economic signals and consequently fails to invest sufficient resources in reducing workplace injuries and illnesses. The economic costs not borne by the employer are borne by the employee or, as is often the case, by society through public insurance and welfare programs; in addition, the numbers of injuries and illnesses and the associated costs are greater than they could be.

Conclusion. OSHA believes that there are no nonregulatory alternatives that adequately protect construction workers from the adverse health effects associated with exposure to the chemicals regulated in this rulemaking. Tort liability laws and Workers' Compensation provide some protection. but due to market imperfections they have not been sufficient. Some employers have not complied voluntarily with standards recommended by professional organizations. The deleterious health effects resulting from continued high levels of exposure to hazardous substances require a regulatory solution.

5. Technological Feasibility

Introduction. This section presents supporting data on the technological feasibility of complying with proposed permissible exposure limits (PELs) for the construction industry. Activities with potential airborne or dermal exposure to the substances to be regulated were identified across all categories of construction establishments and for different types of construction projects. Almost one hundred specific activities were evaluated for potential exposures and the appropriate means of protection. The activities and applicable control methods are described below.

Consistent with OSHA's methods of compliance hierarchy, engineering controls are recommended whenever they are feasible. In construction these include portable exhaust hoods, fans, fresh air blowers, enclosure of the worker or operation, equipmentmounted dust catchers, vacuum cleaning, and water spraying for dust suppression. For most activities, the proposed PELs can be met through a combination of engineering controls and appropriate work practices. Where engineering controls and work practices are infeasible or insufficient, respiratory protection may be used.

Many activities occur outdoors with natural ventilation. This helps to keep exposures low but does not ensure that exposures will be below the proposed PELs. For example, high exposures to lead result from the outdoor grinding, blasting, burning, or cutting of surfaces coated with lead-based paints.

Activities with Exposures—Abrasive Blasting. Abrasive blasting involves the removal of paint, dirt and other substances from surfaces that require cleaning prior to the application of a protective coating. Workers are exposed to the particulate matter generated by the blasting agent and from the surface material.

Four different types of abrasive blasting activities were identified based on the type of blasting agent. Abrasive blasting can be done with sand, aluminum oxide, steel shot, or slag, depending on the application.

In abrasive blasting operations using sand the operator would be exposed to silica (crystalline quartz and respirable dust) as well as concentrations of nuisance particulates. Abrasive blasting with aluminum oxide can cause exposures to aluminum metal dust in addition to silica and inert dust exposures. Abrasive blasting with steel shot or slag may involve exposures to iron oxide dust.

The use of blasting agents will generate additional exposures to substances contained in the surface material and in surface coatings, such as paint, that may be present. These may include lead, iron oxide dust, chromium metal, wood dust, and other particulates.

In the open-air type blasting which occurs commonly in construction, contamination of the general work area can occur if the blasting work is not contained. The blasting crew, including the operator and cleanup personnel, may be exposed to high dust concentrations depending on existing wind conditions. Open-air work makes it difficult to control worker exposures to airborne particulates, especially to the blasting operator. In order to control the exposures, vacublast units which incorporate local exhaust ventilation at the point of operation can be added as an integral part of the sandblast equipment, and a sandblast hood with corresponding supplied air system can be used. In addition, screens and partitions and the use of dust suppressants during dry sweeping of used blasting agents are work practices that reduce the operators' exposure and limit exposure to workers in adjacent areas of operations.

A NIOSH Health Hazard Evaluation reported the workday exposure results obtained by a private industrial hygiene consulting firm during the sandblasting of the Golden Gate Bridge in San Francisco, California in 1981 [1]. Two air samples for lead and one air sample for crystalline silica were collected. The lead concentrations of the two samples collected outside the worker's suppliedair hood were 5.54 mg/m³ and 8.42 mg/m³. The exposure to crystalline silica inside the hood was 0.218 mg/m³. The total dust obtained from the sample inside the hood was 2.74 mg/m³.

The exposure to the worker occurred because the facepiece seal became ineffective and the lens of the helmet had to be replaced. NIOSH stated that "in analyzing the data, it seemed evident that excess exposures to lead and silica could occur, but that proper work practices which included the use

of the two lens hood should take care of the potential health hazard."

CONSAD evaluated worker exposures to lead and silica quartz dust during the sandblasting of interior metal walls made of corrugated sheet metal at a coal preparation plant near Waynesburg, Pennsylvania in July, 1990 [2; Firm 32]. A crew of ten people was involved in the work and seven of these did sand blasting.

The results of the personal samples for lead indicated that the concentrations inside the hood were less than $18 \mu g/m^3$ for each worker. The 8-hour TWA exposures were less than $8 \mu g/m^3$.

The sampling results for the exposures to respirable silica quartz dust indicated airborne concentrations outside the hoods that ranged from 0.09 mg/m³ to 1.2 mg/m³. The resultant 8-hour TWA exposures for the workers ranged from 0.08 mg/m³ to 0.44 mg/m³. The controls in use provided workers with sufficient protection from the levels of airborne respirable silica quartz dust present.

All seven of the sand blasters wore supplied-air helmets and capes. The air supply was provided from an on-site compressor. All employees were wearing safety glasses, hard hats, and hearing protection. No other exposure control measures were utilized. It can be concluded that all of these workers were within the proposed permissible exposure limits and that exposures during abrasive blasting with sand can be adequately controlled with available technologies.

The use of aluminum oxide as an abrasive agent during compressed air blasting provides certain surface preparation characteristics that cannot be achieved with other materials. Workers using aluminum oxide must be protected to the same degree as in other blasting operations with a focus on the airborne exposure to the metal dust generated and to the contaminants contained on the work surface. The exposure potentials and capabilities for control are similar to those for sandblasting. Controls include enclosure of the activity, equipment with built-in exhaust ventilation, dust suppressants, and supplied-air hoods. These methods of protection can ensure that exposures are kept below the proposed PELs.

The use of steel shot blasting is common for the cleaning of concrete surfaces. The shot blasting activity is enclosed within the area of the blasting machine. Machines are commercially available that operate continuously with recycling of the shot pellets. Due to the dusty nature of the operation, workers may be exposed to silica and other

substances present in the surface to be blasted. In addition to dust-controlling machinery and temporary enclosures, exposures can be controlled through the use of dust suppressants and suppliedair hoods.

Worker exposure to total silica dust was evaluated by CONSAD during the preparation of a concrete floor prior to coating. This activity was observed during a site visit near Harrisburg, Pennsylvania in July, 1990 [2; Firm 29]. The assessment consisted of sampling of workers while operating a Blastrac portable shotblast system to clean a concrete surface of approximately 1,600 square feet. The shotblast unit contained a vacuum system for collecting

generated debris.

Samples were collected on the shotblast operator and two other workers in the area and were analyzed for quartz. It was reported that the samples contained an average of 30 percent quartz. The total dust samples for the shotblast operator resulted in 8hour time weighted averages of 10.0 mg/ m3 and a 12.0 mg/m3 exposure during sampling. On the basis of the average percentage of silica quartz determined from the samples, exposures to the shotblast operator exceeded the proposed 8-hour TWA standard for total silica quartz dust. The shotblast operator wore personal protective equipment that included a disposable dust respirator, safety glasses/goggles. and safety shoes. The disposable dust respirator was adequate for protection from nuisance dust but was inappropriate for this particular application. General ventilation was provided from a small wall fan that was in constant operation. No other control measures were observed. Adequate protection from the silica quartz dust could have been achieved through the use of appropriate respiratory protection.

Abrasive blasting activity may also involve use of a slag (also commonly known under the trade name "Black Beauty") as the abrasive material. The slag consists of iron oxide and silica (quartz). Workers performing this activity have the potential for exposure to the surface coating, surface components and the abrasive. The engineering and work practice controls discussed above are also applicable to this activity and have been successful in keeping worker exposures below the

relevant proposed PELs.

Worker exposures to lead dust and other particulates were evaluated by CONSAD during the abrasive blasting of a bridge near Scranton, Pennsylvania in April, 1990 [2; Firm 15]. The operation involved compressed air blasting of a

bridge containing a lead-based paint. The abrasive agent used was "Black

Two abrasive blasting workers were evaluated for their exposure to lead dust during the actual blasting activity. Three individuals characterized as blaster, flagman, and clean-up laborer were also evaluated for nuisance particulates.

The airborne lead dust exposures of the blasters were evaluated as 0.040 mg/ m3 for a 346 minute sample and 0.250 mg/m³ for a 328 minute sample. The determination of the exposure to nuisance particulates revealed that one of the blasters and the flagman were exposed to airborne total dust concentrations of 2.53 mg/m3 and 1.89 mg/m3 on an 8-hour TWA basis. respectively. The clean-up worker was exposed to an 8-hour TWA total dust concentration of 42.75 mg/m3.

The abrasive blasters used personal protective equipment that included airsupplied helmets, full body covering. gloves, and safety shoes. The flagman and clean-up laborer wore a dust mask and a half-mask cartridge respirator, hard hats, and safety shoes. In this project, use of appropriate protective equipment kept worker exposures below

the PELs.

Worker exposure to lead dust and particulates not otherwise regulated (PNORS) were evaluated by CONSAD during a bridge renovation project in Pittsburgh, Pennsylvania in June, 1990 [2: Firm 31]. A work crew of six people was engaged in the bridge work. Of the six workers, two of the workers were engaged specifically in the abrasive blasting aspect of the work. Again, the abrasive agent "Black Beauty" was

The two blasters were assessed during a two-day period for exposures. Samples were collected from both inside and outside the blasters' protective hoods. The results of the samples indicated that inside the hood, airborne lead concentrations ranged from less than 0.011 mg/m3 to under 0.015 mg/m3. The translation of sampling period exposures to 8-hour TWAs resulted in full shift concentrations of less than 0.008 mg/m³. The samples taken outside of the hood indicated potential lead exposures that ranged from 0.036 mg/m3 to 1.10 mg/m3. The equivalent 8-hour TWA concentrations were evaluated as being up to 0.264 mg/m3. On the basis of the determination derived from inside the hood measurements, both of the abrasive blasters were within the proposed standard for lead.

These same two workers were also evaluated for their exposure to total dust. The analytical results indicated concentrations inside the hood of 0.70

mg/m3 and 4.49 mg/m3 for each of the blasters on an 8-hour TWA basis. The proposed PEL for PNORS is 15 mg/m3. It can be concluded that the blasters were within the proposed total and respirable dust standards for PNORS.

Specific measures were taken to minimize exposure to the dust generated during the blasting operation. Prior to the commencement of work, a dust curtain was built around the blasting operational area. In addition, personal protective equipment was used by the work crew that included: respiratory equipment (supplied-air helmets with capes or disposable dust respirators). work gloves, hard hats, and hearing protection. The air supplied for the blaster helmets was provided by a compressor on site.

Roofing and waterproofing operations. Several specific activities involved in these operations were evaluated individually based on the types of substances present and the potential for exposures. These activities include: application of an asphalt roofing system, application of single ply membrane systems, application of polyurethane roofing systems. application of modified bitumen roofing systems, application of asphalt waterproofing, and tear-off operations.

An asphalt built-up roof system involves the use of hot asphalt as the cement and sealer for the roofing system. In a built-up system, roofing paper is rolled out over the roof's surface in sufficient layers to meet the specifications of the contract (e.g., 4, 5, or 6 ply roof). Hot asphalt is pumped from the asphalt heating kettle and mopped on the adjacent seams to cement the layers. This is followed with the mopping of asphalt over the entire roof surface. Exposures to asphalt (and its benzene soluble components) are likely during the mopping process and also to any workers at the kettle during the heating of the asphalt.

Worker exposures are not likely to exceed the proposed PEL of 5 mg/m3 at the mopman and kettleman operations. Engineering controls to reduce the mopman's exposure do not appear to be practical and therefore a respirator would be required in potential overexposure situations. A half-mask respirator equipped with organic vapor cartridges would provide adequate protection. Insulating the pipes from the kettle or tank truck to the roof or reducing kettle temperatures will likely reduce the kettleman's exposure. Keeping the temperature of the kettle as low as possible can help keep worker exposures below the PEL.

A study sponsored by the National Roofing Contractors Association and the Roofing Contractors Association of Southern California evaluated both hot asphalt and hot coal tar pitch exposures to roofing workers in 1981 [4].

The study consisted of the collection of 211 personal samples (98 percent from hot emissions) from 16 work sites. Analyses of the pitch and asphalt samples indicated that the majority for both types of materials was below a total particulate concentration of 5 mg/m³. Other findings from the sample analyses regarding benzene solubles were that (1) 74 percent of the kettlemen samples exceeded 0.2 mg/m³, (2) 49 percent of the total pitch samples and 37 percent of the asphalt samples were below 0.2 mg/m³, and (3) 20 percent of the samples exceeded 1.0 mg/m³.

It was concluded based on observations during the sampling that the roofing industry could take steps to insure that 80 percent of the workers would be below a benzene soluble limit of 0.2 mg/m³. The recommendations to accomplish this included: (1) maintaining the prescribed hot material temperature, (2) selecting appropriately sized equipment and repairing broken equipment, and (3) training workers to incorporate work practices to minimize exposure potential (e.g., working upwind).

The study also concluded that reducing all exposures to below 0.2 mg/ m3 without the use of respirators would be a difficult task. The factors cited for this were: (1) uncontrollable site ventilation-some workers could not avoid exposure because of wind direction and work pattern, and (2) some tasks involve a high exposure potential. The data indicated that exposures for virtually all workers would be below the proposed PEL of 5 mg/m3. A remedial action sufficient to control overexposures is the use of a filter mask for workers known to be exposed to excessive hot emissions.

NIOSH conducted an environmental survey during the application of a petroleum asphalt roof at a site in Houston, Texas in 1983 [3]. The survey was conducted during a two day period. Petroleum asphalt plugs were melted in a heated metal container. The liquified asphalt was transferred to a hot application vessel and mopped on to the prepared roofing surface.

Eleven samples were obtained during the two day period and evaluated for benzene solubles. The airborne concentrations ranged from 0.110 mg/m³ to 1.440 mg/m³. The highest airborne concentration reported was incurred by the kettleman.

A number of measures recommended by NIOSH to minimize contact with pitch would apply to asphalt as well. These included: (1) roofers should stay upwind of the pitch fume as much as possible, (2) showers should be taken after work each day and workers should have a change of clothes after showering, (3) workers should wear clean clothes each day, (4) workers should use waterless cleansers, and [5] personal protective equipment should consist of long-sleeved shirts that are tight-fitted at the wrists, full-length pants that extend to the shoes, goggles, gloves, and respirators. Respirators should be approved for protection from organic vapors. The application of these control methods would provide adequate protection to workers and enable compliance with the proposed PEL.

NIOSH conducted an environmental survey for the U.S. Corps of Engineers, Kansas City Supply Depot, in 1983, to evaluate working conditions during a reroofing job [5]. ASTM Type III asphalt was used as the roof cement material. The survey was conducted over a three day period. The asphalt was received in metal containers and placed in a 300 gallon propane-fired kettle for melting. The material was heated to about 450 degrees Fahrenheit and mechanically pumped to the roof. The hot asphalt material was stored in a hot lugger until needed. The lugger was wheeled to the point of application where the asphalt was dispensed into mopping buckets. The asphalt was mopped onto the plies of roofing felt that were previously laid over the roof deck structure. A final flood coat of asphalt was then mopped over the entire surface. This was followed by the application of a layer of gravel that completed the finishing of the roofing surface.

The full shift average exposures to asphalt fume for the kettleman and the crew were 0.83 mg/m³ and 0.31 mg/m³. respectively. Recommendations to reduce exposures included: the scheduling of work to reduce the number of employees exposed, locating the kettle and work areas to reduce exposure to fumes, and keeping the temperature of the kettle at an absolute minimum necessary to meet material specifications.

CONSAD conducted a site visit to assess the exposure to asphalt fume during the heating and application of petroleum asphalt for a 4-ply built-up roof system in Washington, D.C. in January, 1990 [2; Firm 01]. Four workers were monitored during the heating and hot asphalt application. Specifically, these workers can be characterized as kettleman, material handler, paper

setter, and mop man. The sampling results showed worker exposures ranging from 0.06 mg/m³ to 0.85 mg/m³ on an 8-hour TWA basis. None of the four workers had exposures which exceeded the proposed PEL of 5 mg/m³.

The installation of a single ply membrane rubber-based roofing system involves the use of sprayed, rolled, and brushed-on adhesives. These adhesives are applied following the mounting of the insulation to the roof decking and the layout of the rubber roof membrane. The adhesive is sprayed on the back of the membrane and rolled by workers that follow the sprayer. The seams of the membrane are brush coated with a lap seam adhesive and hand rolled. The workers are exposed to the solvents contained in the adhesives, including acetone, n-heptane, n-hexane, toluene, and xylene.

With the natural ventilation present when working outdoors, the likelihood of overexposure to any of the described organic solvents is considered to be minimal. Engineering controls on an open roofing application project do not appear to be practical or feasible and therefore controls would be limited to respiratory protective equipment if necessary. For exposures that are relatively high, disposable organic vapor masks would be appropriate.

NIOSH conducted a field survey to evaluate the potential of worker exposures in the application of a single ply rubber roofing system in Dayton, Ohio in 1983 [6]. Thirteen personal breathing zone samples were taken on two to six workers performing the application as described above over a four day period. The samples were analyzed for the solvents contained in the roofing adhesives: xylene, toluene, acetone, ethyl benzene, and hexane.

The analytical results for the thirteen personal samples were compared to OSHA's proposed standards. It was determined that the combined exposure to each worker was below that allowed by the proposed PELs. This indicates that the exposures to the workers were within OSHA's proposed limits for each chemical and below the relevant mixed exposure limit, and that compliance with the proposed PELs is feasible for this activity.

Other studies by NIOSH as well as data gathered by CONSAD during site visits confirm that exposures to airborne contaminants during the application of single-ply membrane systems are generally well below the proposed PELs [7; pp. 3.18–3.24]. If necessary, workers can be protected from exposures with respirators.

The application of a modified bitumen single ply roof involves possible exposures to solvents, asphalt, and other airborne substances. The modified bitumen roofing membrane is comprised of several layers; a rubberized or plasticized asphalt sheet, a glass fiber or plastic support and a protective film. These membranes are applied by torch fusing, by setting in hot asphalt or by cold setting on a primed surface.

The likelihood of overexposure to airborne contaminants such as asphalt fumes, nuisance particulates, or organic solvents is considered remote in this activity due to the method of application and the outdoor nature of the work. Control options such as local exhaust ventilation on an open roofing application project are not believed to be practical or feasible and therefore controls would be limited to improved work practices and respiratory protective equipment. For moderate exposures, disposable organic vapor masks would be appropriate with potential upgrade to half or full-face organic vapor respirators for elevated exposures.

CONSAD observed the installation of a modified bitumen roof system during a re-roofing project in Washington, D.C. in March, 1990 [2; Firm 08]. The installation procedure was conducted on two consecutive days. During the first day, workers applied a cold-set adhesive to the roof deck and then covered the deck with a layer of roofing paper. This was followed by the setting of a layer of perlite insulation on top of the roofing paper. On the second day of work, the modified bitumen roof membrane was laid out over the insulation and heat set into place. To heat set the roofing membrane, workers used a propane torch heater.

Five workers were sampled for their exposure to the solvents (stoddard solvent, styrene and toluene) used during the application of the cold-set adhesive during the first day of work. On the following day, three workers were sampled for their exposure to asphalt fumes during the installation of the roofing membrane. Sampling duration associated with the tasks of each day's work was approximately four hours.

For the workers engaged in the application of the adhesive, the airborne concentrations of the solvents contained in the adhesive were non-detectable. The three workers engaged in the heat setting of the roofing membrane incurred 8-hour TWA exposures to asphalt fume that ranged from 0.04 to 0.26 mg/m³ on a total particulate basis. It is unlikely that worker exposures during the two days

of this operation exceeded any of the proposed PELs.

The application of polyurethane roofing is similar to that of polyurethane foam insulation applications. Polyurethane systems are generally comprised of two part mixtures that are stored separately in 55 gallon drums. One component may consist of polymeric and monomeric forms of an isocyanate or diisocyanate and the other component consists of a mixture containing the curing agent, catalyst, solvent, and foaming agent. The mixtures are pumped from the drums to the mixing chamber of the spray gun and atomized onto the roof surface to a thickness of several inches.

The spray operator and helper(s) engaged in the foam application are exposed to airborne concentrations of the components of the specific product used. The important components may include: methylene bisphenyl isocyanate (MDI), toluene diisocyanate (TDI), alpha-methyl styrene, and fluorotrichloromethane. CONSAD found no evidence indicating that significant exposures occur during this application.

Roof tear off operations involve the removal of the old roofing materials that may contain petroleum asphalt, fiber board insulation, and asbestos flashing. The removal of the old roof is a manual operation. However, power saws are used to cut the roof into manageable pieces for removal.

Based on the data available for roof tear-off operations, exposure to airborne particulates generated during this activity can be controlled below the PEL if the roof is thoroughly wetted. Dust exposures can be controlled in most situations with the use of water, water spray, and wet sweeping work practices. If exposures exceed the PEL for particulates other than asbestos, then the use of a NIOSH approved disposable particulate respirator would be necessary. These respirators should provide adequate protection during this activity. If the roof consists of asbestoscontaining materials then half-mask respirators with HEPA filters should be

NIOSH conducted a survey to evaluate worker exposures to total dust and benzene solubles during a roof tear-off in Hamilton, Ohio in 1983 [8]. The tear-off work commenced with the breaking up of the old roof down to the insulation. This was done using a power cutter. This was followed by the separation and removal of the old roofing material. In this step, workers pry the old roofing material from the support structure while using shovels and other hand held prying tools. The

material was then carted to the edge of the roof where it was discarded through a plastic chute.

Six breathing samples were collected during the tear-off operation from a crew of thirteen workers. The sampling time ranged from about 31/2 hours to about five hours. The total particulate concentrations that were reported ranged from 2.1 mg/m3 to 13.1 mg/m3. The analytical results also showed concentrations of benzene solubles ranging from 0.6 mg/m3 to 5.3 mg/m3. All six of the workers were exposed to total particulate concentrations less than the proposed limit of 15 mg/m3, and one of the workers exceeded the proposed OSHA standard of 5 mg/m3 for benzene solubles during the tear-off operation. Although the roofing material contained coal tar pitch, the exposure levels are indicative of potential exposures to the benzene-soluble fraction of asphalt fume during similar

NIOSH recommended a number of improvements that could be instituted to alleviate worker exposure to dust during the removal of roofing. It was advised that water should be used to thoroughly wet the surface of the roof prior to and during tear-off. The use of a vacuum system was recommended in comparison to power brooms and power blowers to remove small debris. Roofers should also stay upwind of the dust during tear-off if possible. OSHA believes that these work practice controls would be sufficient to keep exposures during this activity below the proposed PELs. For highly exposed workers, respiratory protection should be worn.

CONSAD conducted a site visit to assess exposures to fibers during roof tear-off operations in Washington, D.C. in January, 1990 [2; Firm 01]. Two employees were engaged in the tear-off operation for the entire shift; both employees were sampled. The roof tear-off activity consisted of using a power cutter to break up the roof into manageable pieces and then prying the material from the deck using hand tools. The waste material was loaded onto a wheelbarrow and transported to the edge of the roof where it was removed from the roof by crane lift.

The sampling was conducted to assess the worker's exposure to fibrous glass dust. The fibrous glass dust was generated from the loosening of the insulation material that was in place below the roofing.

The results of the personal sampling showed that both workers were exposed to total dust at less 0.1 mg/m³ as an 8-hour TWA. Because the roofing was

thoroughly wetted by heavy rain that had fallen the night prior to the sampling, it is assumed that neither of the workers would have exceeded the proposed PEL of 1 f/cc.

Worker exposure to particulates was evaluated during the tear-off operation of an asphalt roof observed by CONSAD [2; Firm 14]. The roof removal included the use of pry bars and a plow-like device to lift off the old roofing and then the transportation of the waste material to a hoist bucket for disposal. The removal of the old roofing was completed in less than four hours.

Personal samples were collected from two tear-off laborers and evaluated for total dust. The sample analyses indicated airborne concentrations of 1.95 mg/m³ and 1.77 mg/m³ for each sampling period of 215 minutes. These individuals were well within the existing and proposed total dust standards.

The application of asphalt waterproofing involves the use of asphalt-based waterproofing products. Workers engaged in this operation are in contact with the waterproofing material and in close proximity to the area of application. The exposure concerns associated with this activity are the asphalt fumes which may become significant in poorly ventilated areas. Exposures may also occur due to the presence of solvents contained in the waterproofing product. These may include: Benzene, ethyl benzene, petroleum distillates (mineral spirits). toluene, and xylene.

Since the worker is in close proximity to the area of application, there is a potential for overexposure to asphalt fume. Engineering controls to reduce worker exposures do not appear practical and therefore a disposable mask with NIOSH approval for organic vapors should be used when overexposures are a possibility. Maintaining the temperature of the waterproofing agent to the minimum required will help to decrease the airborne concentration of fumes produced. Exposures during this activity can be kept below the proposed PEL through the use of appropriate work

protection.

Insulation Installation and Removal.

Applying and installing insulation can cause potential exposures to airborne concentrations of the material involved. Typical insulation materials include: Fiberglass, mineral wool, and foam. Insulating foams may be some type of polyurethane or a urea-formaldehyde product. The manner of applying or installing the insulation can be either a manual or mechanically assisted type operation. In the manual operation, the

practices and, if necessary, respiratory

worker installs the insulation by hand (e.g., the installation of fiberglass batts, the wrapping of pipe, etc.). One mechanically assisted process involves fiberglass or mineral wool blown into place by a pneumatic blower. In another process, an insulating foam is produced and sprayed into place.

Exposures to the solvents, fiberglass, minerals and other particulate matter in installing insulation will be highly variable dependent upon the nature of the job site. Exposures will vary depending on whether or not workers are in a relatively confined area, such as an attic, or in a well ventilated area, such as an open bay structure. When work is conducted in a relatively confined area, a fresh air supply would be likely to eliminate any overexposure to the solvent portions of the various application methods. In confined areas where insulation is being blown in place, it is possible that respiratory protective devices will be required to control the particulate and/or fiber exposures.

There is a greater potential for significant worker exposure to fiberglass and mineral wool dust generated by the blown-in process than in the manual process. There may also be exposures to the substances contained in the mechanically assisted spraying application. There may be additional exposures encountered in the manual process if any adhesives are used to fasten the insulation to equipment, pipes or ducts. These exposures generally consist of the solvents contained in the adhesive.

A study prepared for NIOSH was conducted on polyurethane foam application activities [9]. Personal samples were collected from two workers to determine their exposure to MDI (methylene bisphenyl isocyanate), fluorotrichloro-methane, alpha-methyl styrene, dimethylcyclohexylamine, and total particulates during the foam application. The application of the foam was made to the interior walls of a refrigeration room of a food warehouse that was under construction. A personal sample was also taken on both workers to determine their exposure to 2ethoxyethanol. The 2-ethoxyethanol is reported as not being extensively used during application but was used during a repair period.

The results of this study showed that both of the workers exceeded OSHA's proposed MDI ceiling level of 0.02 ppm during foam application. None of the other chemical substances exceeded OSHA's proposed exposure limit. NIOSH concluded that engineering controls to reduce MDI levels during indoor foam application would be

desirable but because of the highly mobile nature of the spraying operation, engineering controls could not be effectively applied [7; p. 3.27]. NIOSH also stated that the use of conventional fans and ducting would be impractical because of the tendency of foam particles to adhere to surfaces. As a result of these difficulties, NIOSH recommended the use of a Type C supplied air respirator with full facepiece, operated in the positive pressure mode during the indoor foam spraying of MDI.

Another report that was prepared for NIOSH discusses the exposures associated with the application of mineral wool blankets to an effluent combustion gas duct [10]. Two workers were monitored for mineral wool fibers, total suspended particulate matter, and respirable particulate matter. The average airborne concentrations during the work shift for all personal samples were 0.076 f/cc for fiber concentrations, 2.271 mg/m3 for total particulates, and 0.871 mg/m3 for respirable particulates. The exposure concentrations to mineral wool fiber were within OSHA's proposed PEL of 1 f/cc. Approved disposable respirators were supplied to the workers and their continued availability was recommended.

This report also discusses the exposures associated with "blown-in" mineral wool insulation [10]. In the report, two workers were monitored for their exposures to mineral wool fibers and total airborne particulate matter.

The installers used their truck that contained a gasoline-powered blower into which the bagged insulation was emptied. The hopper was tended by one of the workers during the blowing process. The insulation was loosened within the hopper and blown by a centrifugal fan through a hose to a house attic where it was applied. The second worker was stationed in the attic and directed the depth of the insulation applied.

The personal sampling results of the worker in the truck showed the following exposures: Mineral wool fibers, 0.087-0.238 f/cc; particulate matter, 0.910 mg/m3. The monitored results of the worker stationed in the attic were 0.856-1.359 f/cc for mineral wool and 7.76 mg/m3 for total particulate matter. It can be concluded that without the use of disposable respirators the workers' exposure to mineral wool in this study would have exceeded OSHA's proposed fiber standard of 1 f/cc (fiber count based on aspect ratio of 3 to 1). The workers' exposures to the metals contained in the dust were within the respective

proposed limits.

In another report prepared for NIOSH on the same insulation application process [10], the sampling results were reported as 0.035 f/cc mineral wool and 0.01 mg/m³ total particulate for the truck worker, and as 0.552 f/cc mineral wool and 41 mg/m³ total particulates for the applicator. The use of appropriate respiratory protection would enable worker exposures to be kept below the proposed PELs in such conditions.

CONSAD conducted air sampling of a worker involved in the installation of fiberglass batts during the renovation of an institutional facility in Aspen, Colorado in June, 1990 [2; Firm 24B]. The insulation worker placed the batts between the studs and up against one side of a dry wall panel. The fiberglass installer was sampled for 285 minutes.

The results of the breathing zone sampling showed that the insulator had been exposed to an 8-hour TWA concentration of 7.21 mg/m3 total particulate. The airborne concentration during the sampling period was 12.14 mg/m³. This worker's exposure to total dust would be considered in compliance with the proposed PELs. A fiber count exposure estimate was attempted but was not determined because most of the particulates were not fibrous. The fiberglass installer wore a disposable dust mask, hard hat, and safety shoes during the application. This equipment was considered sufficient for protection from exposures above the proposed PELs.

CONSAD conducted personal air sampling during the installation of fiberglass wool insulation in two residential structures in Panama City, Florida in June, 1990 [2; Firm 26A]. Two workers were involved. One of the workers was stationed in a truck and fed the fiberglass insulation into a Volumatic II pneumatic blower. The other worker controlled the application of the insulation within the attic spaces of the residences.

The workers were evaluated for exposure to airborne fiber concentrations at one of the residences and total particulate exposures at the other. The length of the sampling period was 90 minutes for fiber determinations and 106 minutes for total particulates.

Under the NIOSH "B" counting rules, it was determined that the sprayer operator was exposed to airborne concentrations of 1.7 f/cc and 0.3 f/cc during two individual sampling periods. Based on these airborne concentrations, the equivalent 8-hour TWA was determined to be 0.6 f/cc. It was further determined that this worker was exposed to a total particulate

concentration of 11.5 mg/m³ at the second residence. The equivalent of an 8-hour TWA of 10.1 mg/m³ was estimated based on the spraying of four attics per day of equivalent size to the one observed.

Under NIOSH "B" and OSHA counting rules, it was determined that the insulation feeder operator was exposed to 0.4 f/cc and 0.2 f/cc in the two sampling periods. These values were also determined as being equivalent to 8-hour TWA exposure concentrations. The airborne exposure to total particulates was determined to be 0.85 mg/m³ which resulted in an equivalent 8-hour TWA of 0.74 mg/m³. Exposures for both of the workers were below proposed PELs.

The application of fireproofing material is similar to that of insulation. Fireproofing material is applied to steel structural members and the metal deckings of buildings. Fireproofing material that is similar to a mortar or plaster is prepared by filling a mixer with the bagged dry material and adding water. The material is then pumped to the point of application and is sprayed on using compressed air. Workers who are engaged in the mixing process are

during the dumping of the bags into the mixer. Fireproofing applicators are potentially exposed to particulates from the spray and dispersion of the fireproofing material.

exposed to particulates such as gypsum,

plaster of Paris, and calcium carbonate

Mixer areas can be enclosed in wood or plastic on wood studding and placed under negative pressure using a portable exhaust system. By doing so, dust generated during the dumping of dry bagged ingredients would be contained within the enclosure and safely exhausted to areas remote from the operations. If any bulk raw materials are used they should be kept wet prior to adding them to the mixer. Water sprays or wet sweeping should be used to clean up any spilled materials to reduce ambient concentrations of dust. Where these controls are not effective to reduce exposures below the PEL, respiratory protection in the form of disposable dust mask would be required.

While selective solvents may be added to the batches as curing agents, the quantities of such materials are small in proportion to the overall mix. In conjunction with the wet method of application, the likelihood of worker exposures in excess of corresponding PELs is remote.

CONSAD conducted a site visit to evaluate exposures to workers engaged in the application of fireproofing material in Indianapolis, Indiana in March, 1990 [2; Firm 07]. At this particular site, a fireproofing material consisting of gypsum, cellulose, fibrous glass, and less than 3 percent quartz was sprayed on to structural members and exposed steel floor decking. Three crews consisting of four workers were involved in the activity. Each crew consisted of one mixer operator, one spray applicator, and two workers who transported the spray applicator on a portable scaffold. Two mixer operators and two sprayers were sampled for exposures to total silica dust.

The sample results showed that the percentage silica in the dust was less than one percent. The personal samples of the mixer operators were 30.7 mg/m³ and 87.2 mg/m³ on an 8-hour TWA basis. These exposures exceeded both the existing and proposed total dust standards. However, the sample results of the spray applicators were evaluated at 8-hour TWAs of 1.8 mg/m³ and 3.34 mg/m³.

Mixer operators doing this activity have a greater potential for overexposure than do the spray applicators. Mixer operators handle and dump dry material from bags; this activity is the primary source of airborne exposure. However, once the material is wetted in the mixing process. the potential for overexposure is reduced significantly. As discussed above, standard controls and work practices for handling dusty materials should be employed. The use of appropriate engineering controls, work practices, and if necessary, respiratory protection, can reduce worker exposures during this activity to levels below the proposed PELs.

Insulation removal activities can be divided into those involving asbestos and those where asbestos is not present. In addition to asbestos exposure, workers may experience exposures to plaster based materials such as gypsum, calcium sulfate, calcium carbonate and particulates not otherwise regulated. Further, the use of organic solvents and strippers to facilitate removal may involve potential exposures.

Specific regulations exist concerning the removal of asbestos-containing insulation. These regulations outline strict controls when handling asbestos-containing material. The controls include: total enclosure with exhaust (negative pressure) of the work area, wetting of the insulation prior to removal, and use of respiratory protection to help prevent inhalation of fibers. The control of asbestos fibers should ensure compliance with the proposed PELs for other substances.

In the removal of insulation not containing asbestos, the relevant materials involved are generally fiberglass or mineral wool compositions. The manual removal of such materials will generate particulate matter comprised of these materials. Workers engaged in this activity will have the potential for exposure to these substances and other substances that may have to be removed so that the insulation can be accessed, such as gypsum, calcium sulfate and calcium carbonate. Further exposures may be incurred if the insulation is secured by adhesives and organic solvents or strippers are needed to facilitate the removal.

Exposure to airborne particulates during this activity can most likely be controlled through a combination of engineering and good work practice controls. The engineering controls consist of constructing a total enclosure of the work area. Air should be removed from the enclosure by attaching an exhaust unit. Prior to removing the insulation, it should be thoroughly wetted with a water spray to suppress dust generated during the activity. Debris on the floor should be cleaned by wet sweeping work practices. If these or similar controls can be implemented, the use of respirators would most likely not be required.

Painting and Other Exposures to
Surface Coatings. Different activities
causing exposures to paints were
evaluated separately based on
differences in work conditions, control
potentials, and substances present. The
activities identified include exterior
painting of masonry finishes, exterior
painting of wood finishes, exterior
painting on steel, grinding/drilling/
cutting of painted surfaces, interior
application of floor coatings, interior
painting of metal substrates, interior
painting of walls and ceilings, and
surface cleaning and stripping.

The painting of exterior masonry can be performed by the usual methods of application: brush, roller, and spray. The paint is the source of exposure to workers engaged in this activity and the type employed will determine the specific chemical exposure. Alkyd and epoxy type coatings are generally used for this application. The solvents contained in these coatings constitute the primary exposure hazard but unreacted epoxy monomer, e.g., epichlorohydrin, may also be present.

Exterior painting applications (spray, roller, brush) result in at least some exposure to solvent vapors. The degree to which painters may be exposed to solvent vapors is dependent upon several factors: The method of

application, nature of the work area (enclosed space or open area), and employee work practices. In most situations with adequate ventilation, exposures are likely to be below the relevant proposed PELs. When conditions are such that exposures become concentrated, reducing employee exposures will most likely involve the use of respiratory protection because engineering controls are often difficult to implement. For solvent vapors, a half-mask organic vapor cartridge respirator would be sufficient to protect workers from overexposure. Some paints contain chemical substances (epichlorohydrin, methyl alcohol) for which these types of respirators will not provide adequate protection. In this situation, an airsupplied respirator may be necessary.

Some paints also contain substances for which OSHA is proposing a "skin" designation. Two such substances include methyl alcohol and mercury (aryl and inorganic mercury compounds). Natural rubber or neoprene gloves provide adequate skin protection against these substances in most instances.

The exterior painting of wood is assumed to be applied either by brush or roller methods. The coatings used for wood finishes consist of stains, varnishes, lacquers, paints, and primers. The hazardous exposure potential from coating material is likely to be the solvent(s) contained in the product.

In most applications, exposures are expected to remain below the proposed PELs. As discussed above, implementation of engineering controls are often difficult with exterior painting operations. In the event of concentrated exposures, respirators would offer protection from potential overexposures.

The exterior painting of steel can be performed either by brush or spray methods. The type of paint used will be dependent upon the corrosiveness of the environment. Workers engaged in the activity are likely to experience some exposure to the solvent(s) of the product that is applied. The use of epoxy and urethane coatings may also present additional exposure risks to unreacted monomer residues, e.g., epichlorohydrin, methylene bisphenyl isocyanate (MDI), and toluene diisocyanate (TDI).

In construction, most painting of steel is done with conventional air spray equipment. Particulate and solvent vapor exposures in excess of allowable limits are possible due to overspray and rebound if adequate controls are not used. As with other exterior painting activities, implementation of engineering control measures is difficult. Most exterior painting on steel is conducted

with employees wearing respiratory protection. For protection against inhalation of solvent vapors, a half-mask organic vapor cartridge respirator would be required. In the application of two component urethane and epoxy paint systems, operators may be required to wear air-supplied respirators.

Dermatitis and other skin conditions resulting from contact with solvents or thinners and sensitization from epoxy mixtures are potential health problems if skin contact is not minimized.

Substances commonly found in paint for which OSHA is proposing a "skin" designation include: mercury, aryl and inorganic mercury compounds, n-butyl alcohol, and methyl alcohol. Natural rubber or neoprene gloves will provide adequate skin protection against these substances in most instances.

CONSAD conducted air sampling to evaluate the exposures with the use of a two-part epoxy-polyamide paint during a bridge renovation project near Scranton, Pennsylvania in April, 1990 [2; Firm 25]. Three painters were sampled for petroleum distillates (mineral spirits) and xylene while spray painting the structural members of the bridge.

Exposures to petroleum distillates of 0.83 mg/m³ TWA8 were observed for the three painters. The 8-hour TWA exposures to xylene ranged from 0.313 ppm to 1.875 ppm. The maximum level of exposure obtained during sampling was 9 ppm. Worker exposure to these substances was considered to be adequately controlled because airborne concentrations were less than 10 percent of the proposed PELs. The painters utilized personal protective equipment that included air-supplied helmets, coveralls, gloves, and safety shoes.

CONSAD also observed the exterior painting of a steel bridge during new construction of a commuter rail transit line in Chicago, Illinois in May, 1990 [2; Firm 20]. The work consisted of the application of a base coat and top coat by the conventional compressed air spraying method. The painting operation was surveyed over a two day period. The base coat was a two-part epoxy that contained aluminum metal pigment and solvents (xylene and toluene). The top coat product, a two-part polyurethane, contained xylene, n-butyl acetate, cyclohexanone, hexone (MIBK). toluene, and hexamethylene diisocyanate.

One personal air sample was obtained for each of the three components during the base application. The analytical determination for the airborne presence of aluminum indicated an exposure of 0.42 mg/m³ as an 8-hour TWA. The

proposed PEL for aluminum metal dust is 15 mg/m³ on a TWA8 basis.

The exposure to xylene during the base coat application was calculated at 45 ppm TWA8. The airborne concentration of toluene indicated a breathing zone exposure 5.6 ppm TWA8. It was concluded that no exposures above the proposed PELs occurred during this activity.

During the application of the top coat, two of the painters were sampled for each of the substances identified above except for hexamethylene diisocyanate (HDI), for which there is no proposed PEL. The sampling results in parts per million as eight hour time weighted averages are as follows:

Substance	Painter #1	Painter #2	Pro- posed PEL
N-butyl acetate	6.0	5.3	150
Cyclohexanone	0.1	0.1	26
Hexone (MIBK)	8.0	7.5	50
Toluene	0.7	0.6	100
Xylene	20	18	100

It can be concluded that all of the painters sampled during the base and top coat applications were within the proposed individual limits. It can also be concluded that the combined equivalent exposure based on the proposed standards was less than unity and therefore acceptable.

All of the painters under consideration employed respiratory devices. The base coat applicator wore a supplied-air helmet, while the top coat painters used half-mask organic vapor cartridges. The base coater also wore a cape, work gloves, and safety glasses. Both of the top coat painters used work gloves and wore long-sleeved shirts. Only one of the top coat painters utilized eye protection.

Three painters and a flagman were evaluated by CONSAD on April 24, 1990 for their exposure to zinc dust during a bridge renovation project near Scranton, Pennsylvania in which a zinc-based primer was applied [2; Firm 15]. The primer was applied by the conventional compressed air spray method.

The three painters were exposed to airborne concentrations of zinc dust ranging from 3.64 mg/m³ to 11.20 mg/m³. However, since the work was only performed for about an hour, the equivalent 8-hour TWA exposures ranged from 0.33 to 1.17 mg/m³. The flagman was exposed to an airborne concentration of zinc dust of 0.38 mg/m³ during the work period. The proposed PEL for zinc oxide total dust is 10 mg/m³. Although none of the sampled workers had exposures which exceeded

the proposed PEL on an 8-hour TWA basis, if painting operations last longer the potential for overexposure may be possible.

Personal protective equipment needed to protect the painters includes respirators, full body covering, gloves, and safety shoes. This equipment is considered sufficient for protection from overexposures.

Workers that grind, drill or cut painted surfaces are susceptible to exposures generated by the action of the tools on these surfaces. Workers engaged in this activity will be exposed to the dispersed particulate matter of the surface material (e.g., iron oxide, chromium, zinc dust, etc.) and constituents of the paint, (e.g., lead, chromium, and zinc).

The principal dust control technique for grinding operations is ventilation. Portable grinding tools can be effectively exhausted by equipment that is retrofitted directly onto the tool. One such technique that has been successful in controlling dust from grinding is a low-volume high velocity exhaust system. In addition to ventilation, the use of water on grinding, drilling, or cutting operations can also help reduce the airborne particulate generated during these operations. If engineering controls cannot adequately reduce airborne dust concentrations, then disposable dust mask respirators can be used to reduce exposure levels to below those required by the proposed rule.

Investigations of grinding, drilling, and cutting activities by NIOSH indicate that the potential for overexposure to several substances exists. One study of exposures during the power brushing of painted metal surfaces at a Connecticut nuclear power station in 1981 shows that 8-hour TWA exposures exceeded the proposed standards for lead, fron, and total particulates [11].

A 1983 technical evaluation conducted by NIOSH and the Massachusetts Division of Occupational Hygiene assessed lead exposures to workers on the Tobin-Mystic River Bridge project near Charlestown, Massachusetts [12]. Workers were evaluated while scraping lead-based paint with pneumatic and hand tools; airborne concentrations of lead at levels far above the proposed PEL of 50 µg/m³ were common. The use of appropriate respiratory protection, including positive-pressure air-supplied respirators, was recommended to adequately control worker exposures.

In addition to engineering and work practice controls, appropriate respiratory protection should be utilized to ensure that worker exposures do not exceed the proposed PELs for any of the regulated substances that may be present. The potential for airborne levels of lead to reach hazardous levels is often underestimated when dealing with painted surfaces.

During the interior application of floor coatings workers use a number of different coating materials specific to a given application. Flooring coatings include ordinary paint (such as an alkyd), and polyurethane coatings. Whichever coating is selected, worker exposures arise primarily from the epoxy and isocyanate monomers and the organic solvents contained in the coating products.

Floor coating operations that occur indoors may result in excessive organic vapor exposures in worker breathing zones when provisions are not made to supply adequate ventilation. Fresh air should be blown into the work area to dilute solvent vapors. For most of the common solvents found in floor coatings, half-mask organic vapor cartridge respirators provide sufficient protection. Although overexposure to any of the monomeric isocyanates or diisocyanates is unlikely, a supplied-air respirator would be the appropriate form of protection due to poor warning properties (odor threshold) associated with these substances.

Personal air samples were collected by CONSAD from a three man work crew over a three shift, two day period during the applications of epoxy and polyurethane coatings to a concrete floor near Harrisburg, Pennsylvania in July, 1990 [2; Firm 29]. Three individual applications that consisted of one epoxy primer coat, one epoxy levelling coat, and a finish coat of polyurethane were made. Each coating material was a twopart mixture that was prepared in fivegallon containers at the site. The application process requires that each coat of material be allowed to dry for approximately 6-8 hours before the next coat is applied. The workers used longhandled rollers and brushes (for trim work at the baseboards) during application.

During the applications of the epoxy coatings, the workers were evaluated for their exposure to xylene, hexone (MIBK), epichlorohydrin, and propylene glycol monomethyl ether. The airborne concentrations of these contaminants were within the proposed concentration limits during the sampling periods and well under the proposed TWA8 PELs.

This same work crew was also evaluated for their exposure to xylene, n-butyl acetate, and methyl n-amyl ketone during the application of the polyurethane finish coat. The sampling results showed that all of the solvent vapors evaluated were within the

proposed PELs during the sampling period. Xylene was the major contaminant and an airborne concentration of 22 percent of the proposed PEL was measured. Two of the workers were also evaluated for exposure to hexamethylene diisocyanate (HDI), an unregulated substance with no proposed PEL. The airborne exposure to this substance was below the level of detection of 0.00054 ppm.

During the application of the coating system, the workers used personal protective equipment that included respirators (MSA half-mask or full face with NIOSH approved cartridges) and rubber gloves. General ventilation was provided by a wall fan that was operated during the entire application

time.

The interior painting of metal substrates can involve a number of different interior paints. The normal means of coating are applicable to this activity (e.g., brush, roller, and spray). The selection of the particular type of paint and application method will depend on the environmental conditions to which the metal will be subjected. Workers involved in this activity will be exposed to a number of organic solvents.

Interior painting of metal substrates is usually conducted with conventional air spray equipment. As data from two NIOSH studies indicates [11, 13]. exposures to paint mist or total particulates can potentially exceed the relevant proposed permissible exposure limits. Ventilation techniques such as fresh air supply systems or blowers to direct airborne contaminants away from workers can be applied to reduce worker exposures. The use of respiratory protection may also be applied by some painting crew members. For protection against inhalation of the particulate portion of the paint (fillers, binders, pigments, etc.), a disposable respirator will provide adequate protection in most situations. For overexposures to the solvent portion of these coatings, a half-mask organic vapor cartridge respirator would be required. Painters often use a combination half-mask organic vapor cartridge respirator with a mist removing pre-filter. Some paints contain chemical substances (2-Nitropropane, methyl chloroform, trichloroethylene) for which these types of respirators will not provide adequate protection. In these instances, a supplied-air respirator would be necessary.

Painters that are engaged in the use of compressed air spray painting as an application method have a greater exposure potential to the product

solvents and other substances than when using either a brush or roller. Data from NIOSH industrial hygiene surveys [11, 13] and findings by CONSAD from site visits [2; Firms 15, 20, 22, 23, 25, 30] indicate that worker exposures during each of these activities can be controlled to levels below the proposed PELs. The combined equivalent exposures to the organic substances identified were also evaluated as capable of being controlled within the proposed limits.

Workers involved in interior painting of walls and ceilings generally use either a brush or a roller technique, although spray painting is also possible. A house paint commonly used is water based latex, although oil based (alkyd) and epoxy paints may also be employed. There is the potential for workers to be exposed to a number of organic substances and solvents contained in

these paint products.

If there is an overexposure problem when conducting this activity, it most likely would occur during spray application methods. Inhalation hazards are increased due to overspray and rebound. In work situations involving considerable spraying in areas with poor natural ventilation, fresh air should be circulated into the workroom area to dilute solvent vapors. If adequate ventilation cannot be provided, workers may need to wear respiratory protection. A disposable particulate respirator would be sufficient for protection against the paint mist. If there are organic solvents in the coating, then a half-mask organic vapor cartridge respirator would be necessary

Some paints also contain substances for which OSHA is proposing a skin designation. Three such substances include methyl alcohol, n-butyl alcohol, and mercury (aryl and inorganic mercury compounds). Natural rubber or neoprene gloves will provide adequate skin protection against these substances. CONSAD assessed the exposures with the use of an epoxy type paint from a site visit at the construction of an industrial facility in Indianapolis, Indiana in March, 1990 [2; Firm 12]. Two painters were sampled for petroleum distillates while roller-applying an epoxy ester-silica block filler to an interior concrete block wall. Three of the painters were also sampled for exposures to propylene glycol monomethyl ether and xylene while roller applying an epoxy finish coat to

the same interior concrete block walls.

The 8-hour TWA results obtained from the sampling for petroleum distillates were 53 mg/m³ and 26 mg/m³. The proposed PEL for this substance is 1600 mg/m³. The 8-hour TWA

sampling results for exposure to propylene glycol monomethyl ether ranged from 0.42 ppm to 2.36 ppm. The proposed PEL for this substance is 100 ppm. The 8-hour TWA exposures to xylene ranged from 1.0 ppm to 7.3 ppm. The proposed PEL for xylene is 100 ppm.

Worker exposures to solvent vapors were evaluated by CONSAD in May, 1990 during the interior spray painting of structural steel and masonry associated with the new construction of an industrial facility in Indianapolis, Indiana [2; Firm 30]. Eight painters were involved in the activity and three were sampled for Propylene Glycol Monomethyl Ether (PGME) and xylene that were contained in the epoxypolyamide product. Both compressed air and airless spray painting methods were employed.

The 8-hour TWA exposures to PGME ranged from 7 ppm to 8 ppm. The proposed PEL for PGME is 100 ppm. The breathing zone exposures to xylene resulted in 8-hour TWAs that ranged from 20 ppm to 30 ppm. The maximum average airborne exposure received by any of the painters during a sampling period was 41 ppm over a three hour period. The proposed PEL for Xylene is 100 ppm. It can be concluded that worker exposures to these substances were within the proposed standards.

All of the painters wore negative pressure half-mask respirators. The respirators contained pre-filters and organic vapor cartridges. Painters were also equipped with rubber gloves, protective clothing, and safety glasses. General ventilation was provided through the use of large fans which supplied fresh air to the rooms being painted. These fans were placed in the entrance and directed air toward the ceiling.

CONSAD obtained personal samples from five painters of two independent contractors during the painting of the inner surface of a large open air atrium in Milwaukee, Wisconsin in March, 1990 [2; Firms 13A and 13B]. Three of the workers applied a base and/or a finish coat. The other two painters were responsible for the final trim work and decorative painting in which only a finish enamel was used. Brush and rollers were the primary paint applicators, however, one of the painters used a paint sprayer but for less than one hour of application time.

Workers were monitored for airborne exposure to petroleum distillates. The TWA 8-hour equivalent exposures for the three workers involved in the base and/or finish coat application were all below 60 mg/m³. The 8-hour TWAs of the remaining two workers solely

involved in the finish cost application were below 50 mg/m³. The proposed PEL for petroleum distillates is 1600 mg/m³. The painters used protective clothing (overalls, gloves) to avoid direct skin contact with the materials used.

Breathing zone samples were obtained by CONSAD from two painters while engaged in the coating of interior masonry walls of the shower and locker room areas of a building reconstruction project in South Park, Pennsylvania in April, 1990 [2; Firm 16]. The painters used a long-handled roller and a brush to apply an epoxy paint to the masonry block walls. The painting was conducted in relatively confined spaces with very little natural ventilation. Worker exposures to xylene, ethyl benzene, 2-butoxyethanol and petroleum distillates (naphtha) were evaluated.

The results of the laboratory analysis showed that the exposure levels for both painters exceeded the proposed PEL for xylene of 100 ppm on an 8-hour TWA basis. The xylene exposure for one of the painters was as high as 200 ppm during a two hour sampling period. The airborne concentrations and TWA exposures for the other substances sampled were 50 percent or less of the respective proposed PELs. Each of the painters wore a NIOSH approved half-mask organic vapor cartridge respirator which should have provided adequate inhalation protection.

CONSAD also conducted an evaluation of exposures to workers in contact with interior wood coating materials in a small town near Indianapolis, Indiana in May, 1990 [2; Firm 23]. The painting work under consideration was part of a renovation project of an institutional building. Two painters were observed: one applying a lacquer with an airless sprayer and the other applying the same material with a brush. Only the sprayer was sampled.

The breathing zone samples obtained were analyzed for 2-butoxyethanol, the primary solvent in the lacquer. The airborne concentrations surrounding the sprayer during a one hour sampling period ranged from 2.0 ppm to 7.8 ppm. The painting occurred during one-half of the shift and the 8-hour TWA concentration was estimated to be 2.0 ppm. The proposed PEL for butoxyethanol is 25 ppm and the sampled painter was clearly within the proposed limits. The painter wore a halfmask negative pressure respirator with pre-mist filter and organic vapor cartridge.

On another site visit in May, 1990, CONSAD evaluated airborne exposures associated with the interior painting of drywall during the construction of a multi-use commercial building in Chicago, Illinois [2; Firm 22]. Samples were obtained from two painters while applying latex flat wall paint by the conventional compressed air spray method. The work was conducted in a large basement area with little natural ventilation. Worker exposures to titanium dioxide, silica quartz and total dust were evaluated.

Both of the painters were sampled for titanium dioxide for a period of approximately 155 minutes. The analysis of the samples indicated breathing zone concentrations of 0.047 mg/m³ and 0.057 mg/m³. The proposed PEL for titanium dioxide is 10 mg/m³ on a TWA8 basis.

The analysis of the total dust samples determined that they contained 1.2 percent and 2.4 percent silica quartz. The determination of the airborne concentration of total dust indicated that the painters were exposed to dust levels of 12.0 mg/m³ and 23.4 mg/m³. The 8-hour TWA concentrations were calculated as 10.5 mg/m³ and 20.5 mg/m³. Exposures to both of these workers were considered to have exceeded the existing and proposed standards for total silica quartz dust and total dust.

One of the painters employed the use of a half-mask cartridge respirator and the other wore a disposable respirator that was not NIOSH approved for spray paint mists. The painters also wore work gloves and safety shoes. The use of appropriate respiratory protection can ensure that workers' exposures remain below the proposed PELs.

The application of a solvent or organic compounds to concrete, metal, or wood surfaces is a preliminary cleaning step for many other activities. The application of solvents or organic compounds will generally be some form of direct contact method to allow the solvent to clean or work on the surface. The solvent or organic compounds may be used for general cleaning and specific applications.

applications. Control of organic vapors and gases which may be generated from this type of work can be achieved with fresh air supply blowers. Blowers should be located outside the immediate work room area to supply fresh air for dilution of contaminated air. If dilution becomes inadequate to control vapor concentrations at or above the PEL, then respiratory protection should be used. Supplied-air or self-contained breathing units are required for exposure to chlorinated solvents because these solvents have poor warning properties (odor threshold) and organic vapor cartridges have a short service life. Use of disposable half mask organic vapor cartridge respirators would be sufficient for exposures in excess of the PEL for other common organic solvents which

may be encountered (VM&P Naphtha, xylene, toluene).

CONSAD conducted a site visit in January, 1990 to evaluate worker exposure to 1,1,1 trichloroethane during the cleaning of electrical transformer vault (concrete) pads in Arlington, Virginia [2; Firm 02]. Three workers were directly involved with the cleaning, handling and vacuum pick-up of the solvent during the shift. Two alternating washes of solvent and water were performed on each of the three vault pads worked on during the shift.

The activity consisted of pouring the solvent from a five gallon container onto the floor and broom brushing the surface. Two of the three workers were engaged in this task. This was followed by the vacuum pick-up of the solvent which was accomplished by the third worker. Water was then sprayed on to the floor surface from a hand pump sprayer and also broom brushed. This again was followed by vacuum pick-up. Two solvent and water washes were performed on each pad.

The total time that the workers were actually involved with the cleaning activity was 280 minutes. The 8-hour TWA exposures to 1,1,1 trichloroethane obtained from the personal sampling ranged from 63 to 80 ppm. These exposures include the total time of the work shift and zero exposures for the time that the workers were not involved in the cleaning. The average exposures for the time that the workers were involved in the cleaning ranged from 107 to 138 ppm. In any event, the exposures to workers were within the proposed PEL of 350 ppm.

The exposures associated with the use of a paint stripper were surveyed by CONSAD during the painting of a large open-air atrium in Milwaukee, Wisconsin in March, 1990 [2; Firms 13A and 13B]. Two of the painters were involved periodically with the process of paint stripping. These two painters were sampled for their exposure to petroleum distillates from the paint product and were sampled for exposure to methylene chloride (not included in this rulemaking). The 8-hour TWA exposures to methylene chloride were 4.75 ppm and 6.28 ppm. The maximum average level of airborne exposure found was 9.0 ppm during a five hour sampling period. It is believed that similar exposure results would have been obtained if other chlorinated solvents such as methyl chloroform, trichloroethane, or trichloroethylene had been used. If this assumption is correct the equivalent exposure levels would be below proposed PELs for these solvents.

Welding and metal fumes. Many activities in construction produce welding and metal fumes; OSHA has evaluated each type of activity to determine the nature of exposures and the feasibility of controls. The activities include welding or cutting of aluminum, carbon steel, galvanized steel, and stainless steel; burning, cutting or welding on materials with painted surfaces; soldering and brazing; and lead caulking.

Aluminum is typically used for architectural applications but also has industrial applications. The welding of aluminum is generally achieved using an electric arc and shielded with an inert gas such as helium. The cutting of aluminum stock can be accomplished with an oxy-acetylene torch.

During aluminum welding, the contaminants reaching the breathing zone of the welder may include ozone, nitrogen dioxide, aluminum metal fume plus other metallic oxides (zinc. magnesium, iron, copper). Of these contaminants, one of primary concern is ozone [7; p. 3.115]. Ozone is produced by ultraviolet light from the welding arc. Ventilation and work practices should be used to control exposure to welding fumes and gases. Good work practices involve using a properly fitted welding helmet and keeping the welding plume away from the breathing zone whenever possible. The most effective means of controlling worker exposure to airborne contaminants is through the use of portable exhaust ventilation. A properly designed exhaust system and hood will capture welding contaminants at the source before the fumes enter the worker's breathing zone. If exposures to metal fumes and ozone cannot be controlled through the use of ventilation, then respiratory protection may be needed. The minimum level of respiratory protection is a half-mask air purifying unit approved for metal fumes and ozone.

Carbon steel is a common construction material that has many applications. Structural members, masonry and stone supporting brackets, process tanks, and piping are its most common uses. The joining of carbon steel components is achieved using an electric arc with a shielding gas such as carbon dioxide or nitrogen. The application of an oxy-acetylene torch to carbon steel will achieve any cutting demands.

The major component of carbon steel is iron. Therefore, the primary airborne contaminant to which welders are exposed when welding on carbon steel is iron oxide fume. Gases are also produced in this welding process.

Ozone, nitrogen dioxide, and carbon

monoxide are the most common gases formed. These gases usually do not create an overexposure problem unless the work is conducted in a confined area. As with welding on aluminum, ventilation and work practices should be used to control exposures to welding fumes and gases. The most effective means of control is the use of portable exhaust ventilation. Some manufacturers also produce MIG welding units with an exhaust system directly built into the unit. In this unit, the exhaust hose is mounted close to the electrode. If engineering controls (portable exhaust ventilation or tipexhausted welding gun units) do not provide sufficient protection, then respiratory protection should be used to supplement them. The minimum level of respiratory protection would be a halfmask air purifying unit for metal fumes and ozone.

In December 1981, Maryland
Occupational Safety and Health
[MOSH] conducted an investigation of
construction workers that were exposed
to lead [14]. In one case, employees
were involved in the removal of blast
furnace stoves from a steel mill. After
the stoves were removed with the use of
explosives, the workers used oxyacetylene torches to cut each stove's
outer steel jacket into pieces that could
be transported from the site.

Air sampling of these workers showed that their exposure to airborne concentrations of lead ranged from approximately $200 \ \mu g/m^3$ to $500 \ \mu g/m^3$. In this process lead was a by-product in the blast furnace operation and only existed as a surface contaminant. When cutting, the workers used torches four feet long that placed them farther away from the point of fume generation.

CONSAD conducted site visits to evaluate worker exposure to welding fume and metals. The observations at one firm in Indianapolis, Indiana in March, 1990 consisted of the welding (fabricating) of limestone wall support brackets for an office building. Only one welder was observed and sampled while joining (stick welding) short lengths of carbon steel angles [2; Firm 06].

At another site in March, 1990, six crews each consisting of one welder and one grinder were involved in the welding of carbon steel piping for an industrial facility in Indianapolis, Indiana [2; Firm 11]. Shielded metal arc (stick welding) was employed by the workers observed. Two welders were sampled to assess their exposure to iron oxide fume.

The results of the samples obtained at the first site showed that exposure to iron oxide was 1.2 mg/m³ TWA8 and well within the proposed PEL of 10 mg/m³. The samples obtained at the second site indicated 8-hour TWA iron oxide exposures of 0.14 mg/m³ and 0.28 mg/m³. These results also were within the proposed PEL of 10 mg/m³. Further, the workers' exposures were considered to be in compliance with the new PEL for welding fume of 5 mg/m³ and with requirements for additive exposures.

Galvanized steel has applications in situations that demand corrosion protection. The welding and cutting of this type of material would be the same as that of carbon steel (i.e., arc welding,

and oxy-acetylene torch).

The primary metal oxide of concern when cutting or welding on galvanized steel is zinc oxide fume. The same gases (ozone, nitrogen dioxide and carbon monoxide) discussed in previous welding activities are also produced when welding on galvanized steel. The primary method of controlling worker exposures to these airborne contaminants is local exhaust ventilation. This is most commonly achieved with portable exhaust units which capture contaminants at the source. Where adequate ventilation and good work practices are not sufficient to control employee exposures below the PEL, respiratory protection can be used to keep worker exposures below the proposed PELs.

Stainless steel is most often used in applications that demand high resistance and protection to corrosive and contaminating substances (e.g., food and drug processing equipment and piping, nuclear applications, etc.). The welding of the material is accomplished with an arc welder and an inert shielding gas such as argon or helium.

Chromium and nickel are important constituents of stainless steel. The welding and cutting processes typically associated with work on stainless steel do not appear to generate significant amounts of airborne contaminants. However, whether a visible plume is observed or not, significant concentrations of nickel and chromium metal fume may be produced. Therefore, local exhaust ventilation as discussed above should be utilized.

NIOSH conducted an industrial hygiene survey of airborne exposures generated during the welding, grinding and arc gouging of stainless steel at a nuclear power plant in Perry, Ohio [13]. Three personal breathing zone samples were obtained from three workers and analyzed for zinc, iron, lead, nickel, and chromium. The sampling durations were approximately five hours in length. In addition, a consultant of the construction contractor also conducted

a survey of the same processes which NIOSH reviewed. The consultant's survey consisted of obtaining eleven breathing zone samples and measuring for iron oxide, zinc, nickel and chromium. Six personal samples were collected for lead and twenty-two personal samples were also obtained specifically for the determination of the

presence of chromium VI.

The reported concentrations of all of the personal samples were as follows: Zinc, 0.02 mg/m³-0.57 mg/m³; iron, 0.04 mg/m3-9.9 mg/m3; lead, not detected-0.017 mg/m3; nickel, 0.005 mg/m3-0.85 mg/m³; and chromium, 0.005 mg/m³-1.1 mg/m³. The results indicate that although a potential for overexposure exists, adequate ventilation and good work practices can be effective in keeping exposures below the proposed PELs. NIOSH cited vacuuming and housekeeping as important means of reducing dust levels. If necessary, respiratory protection can be used to keep worker exposures below the proposed PELs.

CONSAD conducted a site visit to assess the exposures to chromium and nickel metal fume during the heli-arc welding of stainless steel piping during the construction of an industrial facility in Indianapolis, Indiana in March, 1990 [2; Firm 11]. Three welders were

sampled.

The 8-hour TWA exposure results obtained revealed that exposures to chromium ranged from 0.0015 to 0.0052 mg/m³ and that exposures to nickel ranged from 0.0011 to 0.0036 mg/m³. The average exposure for these workers was relatively low because the inspection requirements of the project reduced the actual arc time. The proposed PELs for chromium and nickel are the same at 1.0

mg/m³.

Burning, cutting, or welding on steel with painted surfaces can potentially produce many hazardous airborne substances. Exposures can be generated in the process of heating a coated steel by using an oxy-acetylene torch or an arc welder. The exposures that are produced consist of the base metal components (e.g., iron oxide, chromium, etc.), the volatized components of the coating (e.g., lead, zinc, chromium, etc.), and the resultant gases that are generated (e.g., ozone and carbon monoxide).

Workers can be adequately protected from lead exposures by engineering controls and respirators that are approved for that purpose. Lead is one of the primary health hazards associated with burning, welding, and cutting activities and is often present in relatively large quantities. The lack of adequate protection for workers is often

due to a lack of awareness of the presence of lead or the erroneous assumption that the amount of lead fumes generated would not create a hazard.

Control of worker exposures to the metal fume and gaseous compounds created during the burning processes can be accomplished by equipmentmounted exhausts on the torches and by portable exhausts used as local ventilation at the point of operation. Screens or partitions between burning operations help reduce exposures to any workers in adjacent areas. Where engineering controls can not adequately reduce exposures below PELs. supplementary respiratory protective equipment can be used. This respiratory protection could range from half-mask respirators to air-supplied systems depending upon the nature of the contaminant and the level of exposure.

Maryland Occupational Safety and Health (MOSH) conducted an investigation after bridge workers were hospitalized for acute lead poisoning [14]. The workers were engaged in the resurfacing of a four-lane highway bridge that was located over a major river. In the course of the normal workday, torch cutting, arc welding, and grinding were performed. Lead overexposures were not expected since the work was performed outdoors and it was believed that normal air currents would disperse the contaminants.

Personal air sampling was conducted on employees that continued to work on the bridge. Airborne exposures of up to 4900 µg/m³ were observed.

Precautionary measures to protect the workers from the potential of this health

hazard were absent.

An article in Welding Journal illustrated several cases which demonstrated the potential hazards of lead in these types of activities [15]. In one case, workers were engaged in the cutting and welding of I-beams in a conversion project of an old power generating station. The work was being done indoors in a wide open area that was thought to be adequately ventilated.

The state of Maryland was notified that the workers involved had been hospitalized for lead poisoning. State health investigators arrived shortly after notification and conducted personal air sampling on workers who had replaced the hospitalized workers. Most of the samples reflected airborne concentrations of lead in excess of 1,000 $\mu g/m^3$, 20 times the proposed permissible level (50 $\mu g/m^3$), with one sample exceeding 1,400 $\mu g/m^3$. There was no indication that any measures were taken to protect the workers from lead exposure.

The Occupational Health Service (OHS) of the New Jersey Health Department initiated industrial hygiene follow-up evaluations subsequent to elevated blood lead levels received from workers involved in construction activities. OHS conducted one such industrial hygiene evaluation at a bridge construction site [7; p. 3.42]. The project involved the rehabilitation of a span bridge, which was fabricated from steel coated with lead chromate paint.

A crew of five ironworkers was engaged in the process of removing and replacing the rivets in the bridge structure. The ironworkers would torch cut the old rivet heads and punch out the remaining part with a pneumatic hammer. The replacement nut and bolt was installed with an impact wrench. Within two weeks of work, all five workers became ill. Two of the workers were hospitalized and treated for lead poisoning. The OHS determined that the source of the lead exposure was the paint coating of the steel and not the rivets which were suspected initially. OHS conducted short-term breathing zone sampling of a burner and a hammer operator. The exposures to lead were 5.956 μ g/m³ and 0.363 mg/m³ for the burner and hammer operator, respectively. The hammer operator's exposure to lead originated from dust generated from the hammering out of the rivets. Several recommendations were made as a result of the evaluation. These included: a lead awareness program for all workers with lead exposure, the use of powered air purifying respirators with HEPA filters, and medical surveillance.

In March, 1988 five of nine workers employed to demolish a bridge in western Massachusetts were diagnosed for lead poisoning [16]. These workers used oxy-acetylene torches to cut apart sections of the bridge. OSHA investigators determined that the bridge coating contained 30 percent lead by weight and that the available respirators were not always equipped with the proper cartridges to protect the workers from lead fume.

CONSAD conducted a site visit in Chicago, Illinois in March, 1990 to evaluate worker exposures to coating materials and fumes generated during the burning/cutting of painted steel [2; Firm 09]. The project consisted of the installation of a new HVAC and sprinkler system as part of the renovation of an office building. The primary interest in this project was the torch cutting enlargement of girder holes and the emissions generated from the paint coating on the girders. Following

the hole enlargement, support plates were stick-welded around the holes.

Two employees were involved in the process. One was responsible for the torch cutting and the other for the welding. Both workers were sampled for iron oxide and lead fume. The 8-hour TWA exposures to iron oxide fume were determined to be 0.16 mg/m3 and 0.30 mg/m3 for the torch cutter and the welder, respectively. The proposed PEL for iron oxide fume is 10 mg/m3. Both of the workers experienced overexposures to lead, based on a proposed PEL of 0.05 mg/m3. The TWA 8-hour determinations were 2.13 mg/m3 and 4.98 mg/m3 for the torch cutter and the welder, respectively. Personal protective equipment consisted of cotton gloves. long sleeved shirts, safety shoes, and welding helmets and shields. The torch cutter had a 12" portable fan situated behind him to blow fumes away from his breathing zone. There also were two air filtration/exhaust units located in the work area.

Soldering and brazing are techniques that are used to join metal pieces or parts. These techniques use heat in the form of a propane, MAPP gas or oxyacetylene flame and a filler metal (tin/ lead compositions, rosin core, and brazing rods) to join materials. Fluxes are used in soldering to remove metal oxides and surface contaminants from the metal surfaces before the filler metal is applied. Potential exposure sources are the heated metal (e.g., copper, iron oxide), the filler metal (e.g., lead, tin oxide and rosin core pyrolysis products) and the flux (e.g., zinc chloride, ammonium chloride, methyl alcohol and ethyl alcohol).

Brazing operations present potentially greater exposure hazards because of heat intensity. Most soldering operations occur at temperatures that are less than 800 °F. The melting point of the filler metals is relatively low (less than 600 °F) and the activity usually does not generate significant concentrations of metal fume. Brazing operations usually occur at temperatures in excess of 800 °F. The temperature of the operation is of major importance since it determines the vapor pressure of the metals that are heated and therefore the potential concentration of metal fumes to which the employee may be exposed. Because most field soldering and brazing work is conducted with a torch, it is difficult to regulate operating temperatures to within recommended limits to reduce the amount of metal fumes generated. In confined areas, portable exhaust ventilation is recommended to remove metal fumes and gases associated with

this type of work. However, worker time weighted average exposures to metal fumes are usually not exceeded due to the limited durations of exposure encountered with soldering/brazing work.

Fluxes are also used to clean the metal surfaces to be bonded. The flux, which may be a solid, liquid, paste, or gas, is designed to remove surface contamination and keep the area clean until the solder metals can be applied. The flux is commonly applied by brushing or rolling directly onto the metals to be bonded. Most of the fluxing compounds do not present a significant airborne hazard but are corrosive to the skin. Therefore, skin contact should be minimized by specific work practices and good housekeeping. Volatile compounds such as alcohols (isopropyl, ethyl or methyl alcohol) are added to fluxes for viscosity purposes. Should a potential overexposure to methyl alcohol exist, an airline or supplied-air respirator is recommended as well as the use of special protective gloves. Methyl alcohol is one substance for which OSHA is proposing a skin designation. A natural rubber or neoprene glove would provide adequate skin protection.

CONSAD evaluated worker exposures to copper, silver, tin oxide and zinc chloride during the soldering of copper pipe joints in a water heater, kitchen sink and bathroom area of a single family house in Panama City, Florida in June, 1990 [2; Firm 26C]. A plumber completed 40 joints in approximately three hours. Tin-silver-copper solder wire (lead free) was used during this application. The soldering flux consisted of zinc chloride. The airborne concentrations of the contaminants obtained in the sample were all well below the proposed limits.

CONSAD conducted another site visit to evaluate exposures to plumbers during the renovation/remodeling of a school building in Bethel Park, Pennsylvania in July, 1990 [2; Firm 27]. One plumber was sampled for exposure to aluminum, copper, lead, silver, and tin while soldering copper pipe joints. When the plumber was not soldering, he was drilling holes for the piping installation. All of the exposures were below the proposed PELs for the individual substances. These exposure determinations were considered to be representative of the soldering activity for an average day.

The use of lead pots for lead caulking activities produces potential exposures to lead fumes. Lead caulking is used in some commercial construction building applications including the sealing of iron waste pipe joints. The use of lead for this purpose requires that it be liquified. The process of heating the lead and its application as a liquid presents possible exposure to lead oxide fume.

Since a lead pot remains stationary during heating, a portable exhaust system mounted near the pot can control lead fume. Appropriate thermostatic control devices can also be installed on the pot to prevent overheating, thus reducing the amount of metal fume. Also, the handling of lead requires that employees follow good personal hygiene and proper work practices to reduce the exposure potential. If respiratory protection is required, a half-mask respirator with NIOSH approved filters would be adequate [7; p. 3.136].

Concrete work. Workers are potentially exposed to a variety of substances when doing concrete, brick, and masonry work. Work activities include patching and resurfacing, sealing and coating, grinding/drilling/cutting, handling mortar or cement, handling and pouring concrete, preparing floors with a chemical stripper, installing concrete forms, and batch mixing of concrete, mortar, and cement.

Concrete patching and resurfacing work can range from the patching of small holes and cracks to a complete resurfacing, Various patching products are available depending on the application, e.g., epoxy resin patching compounds and plastic mortars.

Many patching and resurfacing products contain organic solvents. Epoxy compounds, used extensively in this activity, contain amine compounds (hardening agents) and organic ether compounds which can cause both skin sensitization/irritation and respiratory tract irritation. For this reason, adequate ventilation and good work practice controls need to be implemented to prevent worker overexposures. Blowers, located outside the immediate work room area to supply fresh air, dilute organic vapors and help to reduce exposure levels. There is no indication from the available data that exposures above the proposed PELs occur during this activity. If dilution ventilation should prove inadequate to control vapor concentrations, then respiratory protection would be necessary.

Sealing and coating operations involve the application of products that impart a durable finish to concrete or that seal it from water penetration. The products used for these purposes can be applied by brush, roller, and spray. Workers engaged in the use of these products may be potentially exposed to a range of organic solvents and active

reagents that these products may contain.

Sealing and coating operations that occur indoors may result in excessive organic vapor exposures when provisions are not made to supply adequate ventilation. Fresh air should be blown into the work room area to dilute solvent vapors. If adequate ventilation cannot be provided to the work area, respiratory protection may be necessary. For most of the solvents found in floor sealants, half-mask organic vapor cartridge respirators provide sufficient protection.

NIOSH conducted a health hazard evaluation to assess the health effects of isocyanates during floor waterproofing operations at a Philadelphia hospital in 1984 [17]. The floor waterproofing activities consisted of the following: (1) The caulking of the risers, baseboards, uprights, floors, and walls with a moisture-cured polyurethane sealant, (2) the filling of cracks in the flooring-the aliphatic urethane material used was troweled into place, (3) the application of the deck waterproofing material-one part liquid polyurethane was poured onto the floor, squeegied, and rolled out with a long-handled paint roller, and (4) application of the finish coat-two part liquid polyurethane materials were mixed for about six minutes and applied to the flooring with a long-handled paint roller and/or brush. The waterproofing contained one or more of the isocyanates: methylene bisphenyl (MDI), polymethylene polyphenyl (PAPI), and toluene diisocyanate (TDI).

Five personal samples were taken. No detectable concentrations of the monomeric isocyanates and ethylene glycol were found in any of the samples. NIOSH recommends the use of suppliedair full-face respirators for protection from overexposures to diisocyanates.

CONSAD observed the application of a waterproofing membrane to a concrete floor during the construction of a new building in Pittsburgh, Pennsylvania in February, 1990 [2; Firm 03]. Two employees were involved in the process of troweling the waterproofing membrane onto the floor. Xylene was a primary component and therefore exposures to the substance were evaluated. The analytical determinations for the exposures to xylene were 7.5 ppm and 3.8 ppm on an 8-hour TWA basis. The proposed PEL for xylene is 100 ppm as an 8-hour TWA. The two employees involved in the application process wore rubber gloves to prevent skin contact.

Workers that engage in grinding, drilling, chipping, or cutting on concrete, brick, or masonry can use a variety of tools to perform these tasks (e.g., sawing equipment, hammer drills, chippers, core drills, and jack hammers). Exposures result from the generation of particulate matter and dust. Workers can be exposed to some form of calcium silicate, silica (quartz), and other particulate respirable dusts.

The principal control techniques to reduce worker exposures to dust are ventilation and enclosure. However, airborne dust concentrations can be quite high during this activity; the use of disposable dust masks is very common. In most situations, this type of mask should provide adequate protection.

Worker exposure to silica quartz was evaluated by CONSAD during the construction of an industrial facility in Indianapolis, Indiana in March, 1990 [2; Firm 10]. The activity involved a worker engaged in the cutting of concrete blocks with a 14-inch diamond blade cut-off saw. The saw cutter was exposed to airborne dust containing 8 percent quartz at concentrations of 12.5 mg/m3 and 57.1 mg/m3 during the sampling periods. On an 8-hour TWA basis, this worker's exposure was estimated to be 37.8 mg/m3. Thus, the worker was overexposed to total particulates and exposure to silica quartz respirable dust exceeded the proposed standard.

Personal protective equipment including safety glasses, goggles, cotton work gloves, and respirators should be provided to the employees doing this work. The proper use of this equipment would provide adequate protection from

potential overexposures.

Worker exposure to total silica dust was evaluated during the preparation of a concrete floor prior to coating near Harrisburg, Pennsylvania in July, 1990 [2; Firm 29]. Two workers were sampled while using scarifying tools to clean the concrete floor surface in areas that could not be shotblasted. Samples were collected from two workers and from a shotblast operator. It was determined that the average quartz concentration of the dust samples was 30 percent. The two scarifying workers were exposed to airborne dust concentrations of 73.6 mg/ m3 and 20.1 mg/m3 during the sampling periods. Their exposures were 62.3 mg/ m3 and 5.0 mg/m3 respectively, on an 8hour TWA basis reflecting minimal exposure while not engaged in the activity. On the basis of the percentage silica determined from the samples, the airborne concentrations exceeded the proposed standard for total silica quartz dust.

The workers wore personal protective equipment including disposable dust respirators and safety glasses. The disposable respirators were considered adequate for nuisance dust and silica. A small wall fan provided general

ventilation to remove contaminants during the work period.

Mortar and cement are common products in the work of bricklayers and masons. Workers apply mortar when working with concrete block, brick, and stone. The primary components of mortar consist of portland cement and sand. The potential for overexposure to dust is present at mixing work stations. The potential for dust exposures in excess of corresponding PELs is unlikely after mixing with water. If curing compounds are added to the mix, workers may be exposed to organic solvents. However, the potent al for overexposure to solvent vapors during this activity is remote.

Handling or pouring concrete and troweling and leveling concrete do not create significant airborne exposures. Concrete is normally delivered to the pouring site pre-mixed. As a result, workers are not exposed during the pouring, leveling, and finishing of concrete. Workers that are engaged in the application of curing compounds to the poured concrete may experience exposures to organic solvents contained in such products. The potential for overexposure to solvent vapors during

this activity is remote.

Worker exposure to solvent vapors were evaluated by CONSAD during the spray application of a concrete curing compound in Chicago, Illinois in May, 1990 [2; Firm 19]. Air samples were collected from one laborer during the application of a concrete curing product with a hand-held sprayer. The primary solvent was mineral spirits. The exposure determination from the personal sampling resulted in an 8-hour TWA of 10.6 mg/m3. Air concentrations of the mineral spirits for three time intervals of less than two hours each ranged from 31 mg/m3 to 45 mg/m3. The proposed PEL for petroleum distillates (mineral spirits) is 1,800 mg/m³ TWA8. Personal protective equipment worn by the employee included a half-mask organic vapor cartridge respirator, rubber gloves, and eye protection.

At the construction of a hotel in Denver, Colorado in June, 1990. CONSAD was present during the pouring of concrete and the application of a curing material to a concrete surface [2; Firm 24A]. As the pouring progressed and the concrete started to set and harden, it was worked with power floats. A short time before the pouring was completed, one worker used a hand pump sprayer to coat the concrete with a curing agent. Air samples were collected and analyzed for n-hexane. Two workers were sampled. One worker was the curing

material applicator and the other was a floater working in the area of the applied material. The airborne concentrations of n-hexane obtained during sampling periods of one to three hours (representing the highest potential exposures) were less than 2 mg/m³ for each of the workers. The proposed 8-hour TWA PEL for n-hexane is 180 mg/m³.

Preparation work on concrete floors using chemical strippers is generally done to remove surface impurities or prior coatings. Application of the chemical strippers is done manually in a number of ways, e.g., direct pouring of stripper onto the surface followed by brushing or rolling. Concrete cleaners and strippers may contain mineral acids, organic acids or organic solvents.

Airborne contaminants generated from most activities involving preparation work on concrete floors can be controlled by implementing engineering controls. To prevent exposures to organic vapors and acid mists associated with this work, the use of fans to supply fresh air and to blow contaminants away from workers appears practical. Where exposures cannot be controlled within allowable limits by engineering controls. respiratory protection must be provided. For potential overexposures to the most common stripping agents (phosphoric acid, MEK, toluene, MIBK) the use of a disposable half-mask organic vapor cartridge/acid gas respirator is necessary.

The preparation and installation of concrete forms can cause exposures to several substances. Concrete forms are casings that hold and shape poured concrete. These forms are generally made of wood but can be metal as well. To prevent the concrete from adhering to the forms and to facilitate removal, the forms may be coated with oils. These oils generally consist of petroleum distillates, naphtha, xylene or some combination of organic solvents. Workers that engage in this activity are potentially exposed to these substances.

Since the majority of this work occurs outdoors and is of limited duration, exposures can be controlled by implementing good work practices (working upwind and not overspraying). If exposures still exceed the PEL, a half-mask organic vapor cartridge respirator should be used.

Batch mixing of concrete is normally accomplished by adding the ingredients (portland cement, sand and gravel) to water in a mixer. Significant airborne dust concentrations can be produced during this activity. The primary source of exposure occurs during the handling of bagged material. Most batch mixing

operations require the operator to manually dump dry portland cement into the mixer after opening bags with a utility knife. Sand is usually stored in bulk form near the mixing area and is added to the batch by shovel. It is not uncommon to find the mixer operator covered with dust from the manual handling of raw materials. Mixer operators may be required to wear a single use or disposable dust mask to ensure that exposures are kept below the proposed PELs. Airborne dust concentrations can be reduced with isolation, by using a water spray on the bulk sand pile, and through the implementation of wet sweeping practices in the mixing area.

CONSAD observed the batch preparation of concrete and mortar during the construction of an industrial facility in Indianapolis, Indiana in March, 1990 [2; Firm 10]. Two workers were sampled for their exposures to silica and total dust while engaged in the mixing process. The prime activity of these workers was adding portland cement, sand, gravel and water to the two- and four-bag capacity mixers. The portland cement was contained in bags while the sand and gravel were piled on the ground near the mixers.

The sample determinations revealed that the workers were exposed to airborne concentrations of 12.4 mg/m³ and 13.2 mg/m³ of total dust containing less than one percent silica quartz on an 8-hour TWA basis. The primary component of the dust generated was portland cement and the proposed PEL for this substance is 10 mg/m³.

The employees were provided with personal protective equipment that included glasses/goggles, cotton work gloves, and respirators. This equipment provided adequate employee protection.

CONSAD observed the installation procedure of a terrazzo marble floor during the construction of a large multiuse commercial building in Chicago, Illinois in May, 1990 [2; Firm 21]. Primary tasks included the preparation of the flooring material and the grout. The components of the flooring material consisted of marble chips, white portland cement and sand. The components of the grout consisted of portland cement and color pigment. These materials and water were added to a two-bag mixer. CONSAD evaluated the exposures to silica quartz and to total dust for the individual responsible for the mixing operation.

During the sampling period of approximately four hours, the mixer operator was exposed to a total dust concentrations of 5.25 mg/m³. Exposures to total dust and silica were within the proposed limits. CONSAD observed that

the bulk storage piles of marble chips and sand were periodically wetted to suppress the dispersion of dust in the work area.

The preparation of mortar is analogous to that of concrete. The preparer fills a mixer with portland cement and sand. The exposures occur from filling the mixer with cement from bags. There is also the potential of exposure to silica (quartz) during the sand addition. The control measures discussed above also apply to batch mixing of mortar and cement. These controls include enclosure of the mixing area, ventilation, use of a water spray on bulk sand piles, and implementation of wet sweeping work practices. Where these controls fail to reduce worker exposures to within acceptable limits. an air-purifying dust respirator would provide adequate protection.

Carpentry and Glazing. Activities during carpentry and glazing operations with potential exposures to airborne contaminants include the application of caulking compounds and sealants, bonding and gluing activities, cutting wood, applying wall and floor materials, and sanding.

Caulking involves the use of various caulks and sealants to fill cracks or spaces left by joints from general construction activities such as the installation of windows, or caused by the movement of material, such as asphalt pavement cracks. Generally, the caulking or sealant is applied manually with a spring-loaded caulking gun.

Workers using caulks and sealants are potentially exposed to solvents contained in these joint-filling materials but it is unlikely that overexposures to solvents will occur during normal use. Several commercially available products contain tin and mercury compounds. These substances may be present in small concentrations, and workers should protect skin areas where contact may occur.

While caulking compounds contain many solvents as ingredients, carriers, or drying agents, it is unlikely that workers would be overexposed to corresponding PELs during the normal application of these materials. The method of application is slow by nature and therefore a large volume of materials can not be used over a normal work day. In addition, the composition of the solvent portion of the caulking compound is such that it does not represent a significant source of exposure.

Bonding and gluing activities are common in the carpentry trade. There is a potential for exposure primarily to the solvent(s) contained in the adhesive. Typical applications would include: counter top lamination, panelling installation or the joining of work pieces.

As with the application of sealants and caulking, the likelihood of worker exposure in excess of corresponding PELs for the organic solvent components of glues and adhesives is believed to be remote. The relatively small percentage of the solvents in the adhesives, the normal mechanical methods of application, and the small total volume of materials utilized in a given work day would normally maintain worker exposures below proposed limits. However, in situations where single applicators spend the majority of their day applying adhesives, especially in relatively confined areas, exposures in excess of PELs may occur. In these instances, fresh air supply blowers can be used to dilute the airborne concentrations to within acceptable limits. In circumstances where this can not be achieved, organic vapor respirators would be required. In addition, some of the materials which might be present in a given adhesive, such as cyclohexanone, would require special gloves such as neoprene, to reduce the skin absorption hazard.

The potential for exposure to soft and hard wood dusts exists during the cutting of wood. The exposure may become significant when workers using power saws are dedicated to this activity for an extended period of time. This is not believed to be a situation commonly found in construction work.

When equipment is dedicated to full time operation local exhaust ventilation should be supplied in order to control the operator's exposure. Work practices such as using dust suppressant compounds prior to dry sweeping will reduce exposures during clean-up. In rare instances where these practices do not substantially control exposures, respiratory protective equipment such as a disposable dust mask would be required.

CONSAD conducted personal air sampling to evaluate the wood dust exposures associated with the framing of a 1,200 square foot single family residence in Panama City, Florida in June, 1990 [2; Firm 26B]. Two carpenters sampled used a hand-held radial saw to cut pine boards and planking throughout the day.

Airborne concentrations of 0.93 mg/m³ and 0.30 mg/m³ were determined for each of the samples obtained. The equivalent 8-hour TWA concentrations were slightly lower at 0.87 mg/m³ and 0.28 mg/m³, respectively. These workers were exposed to less than 20 percent of

the permissible exposure level allowed by the proposed standard.

Applying floor and wall coverings is a manual activity in which the worker is directly in contact with the floor/wall materials and any primers, adhesives and grouts used. Flooring materials may be ceramic, hardwood, linoleum, or carpeting. To help prevent worker exposures to organic solvent vapors, ventilation is the method of control believed to be most practical for this activity. Blowers can be located outside the immediate work room area to supply fresh air for dilution of contaminated air. If dilution becomes inadequate to control vapor concentrations within the PEL, then half-mask air-purifying (organic vapor) respirators are recommended.

Some adhesives contain organic solvents for which OSHA is proposing a skin designation. One substance commonly encountered with this designation is cyclohexanone. A butyl rubber glove can provide good protection when handling this substance.

In the laying of a ceramic floor, an adhesive is mixed and troweled on to the floor surface. The tiles are placed and the adhesive is allowed to set. This is followed by the filling of the tile joints with grout. Linoleum flooring is generally sold with a self-adhesive backing that is protected with a thin film of plastic or cellophane. The removal of the protective film exposes the adhesive and allows the direct application of the flooring.

However, the installation of ceramic tile still requires the manual application of an adhesive. The primary exposures to workers in these activities arise from the contact and use of flooring adhesives and any specialty grouts. The products used for these applications generally contain one or more organic solvents.

CONSAD conducted a site visit in May, 1990 to observe a commercial carpeting installation near Chicago, Illinois and to perform personal air sampling of the workers [2; Firm 17]. The installation involved the application of an adhesive to the flooring prior to laying the carpet. VM&P naphtha was the primary solvent component of the product. Two workers were sampled during the application. Neither of the employees was equipped with personal protective equipment and no engineering or administrative controls were observed.

The 8-hour TWA equivalent exposure determinations were the same for both employees at 3.3 ppm. The airborne concentrations were also approximately the same for the individual sample

times. The maximum exposure level determined was 4.0 ppm. The proposed PEL for VM&P Naphtha is 300 ppm.

CONSAD also conducted air sampling during the installation of ceramic wall tile to evaluate the associated exposures in Pittsburgh, Pennsylvania in February, 1990 [2; Firm 03]. On this project, a tile setter troweled on an adhesive to a concrete block wall prior to the setting of the ceramic tile. Two finishers worked after the tile was set and applied the grout. All three of the workers were sampled for their exposure to VM&P Naphtha. The 8-hour TWA exposures for each were less than 1.0 ppm.

Worker exposure to carpeting adhesive solvents was evaluated by CONSAD during carpeting installation at a college dormitory in Pittsburgh, Pennsylvania in February, 1990 [2; Firm 04]. The primary solvent component of the adhesive was VM&P naphtha. One worker was sampled during an application period of approximately two hours. The airborne concentration of VM&P naphtha during the period was determined to be 3.7 ppm.

Sanding of wood surfaces may be accomplished either by hand or by the use of electrically driven reciprocal and belt sanding equipment. The potential exposure to wood dust exists with either method but may be more severe when power equipment is used and the activity duration is long.

When using electrically driven or pneumatic sanding equipment, worker exposures to dust can be controlled by exhausting air at the point of operation. Mechanical sanding equipment is commercially available with built-in exhausts in the design of the unit. This captures dust before it enters the worker's breathing zone. To clean the work area of material which has reached the floor, either dust suppressant compounds or wet sweeping practices should be implemented.

Hand sanding operations may be quite dusty but are usually of limited duration throughout a work day. Time weighted average exposures would most likely be below the proposed PELs for the corresponding dusts generated. If the potential for an overexposure exists, the use of a NIOSH approved disposable mask would provide adequate protection.

Sanding of drywall surfaces is generally done by hand. Workers that engage in drywall installation are likely to be exposed to the plaster material (gypsum-calcium sulfate) when sanding the dried joint compound.

A significant amount of dust can be generated during this activity; the degree of worker exposure depends on several factors. If the installation process is done by one worker then the time spent sanding may be intermittent and represent only part of the work shift; the resulting TWA exposure is likely to be within proposed limits. When several workers are sanding in close proximity to one another in an area without adequate ventilation and the sanding is done continuously for most of the work shift, then the potential for overexposure is increased.

Power sanding tools can be equipped with dust collection devices to reduce worker exposures. During power sanding and hand sanding, ventilation can reduce airborne concentrations through general dilution. Appropriate work practices can play a critical role in preventing excess exposures. The work area should be kept clean; the use of dust suppressants and vacuuming are effective means for keeping particulates out of the air. Exposures during clean-up operations may exceed those during actual sanding work if proper housekeeping measures are not taken. If engineering controls and work practices are not able control exposures adequately then respiratory protection

would be required.

Worker exposure to hardwood dust was evaluated by CONSAD during the sanding of a maple gymnasium floor in Bethel Park, Pennsylvania in July, 1990 [2; Firm 27]. The floor sanding was a one-man operation and was conducted for a full 8-hour day. The sanding machine was equipped with a dust collector to capture dust which appeared to be effective. The sander used personal protective equipment that included a dust mask (NIOSH approved), ear plugs, and safety shoes. It was observed that the main source of exposure occurred while emptying the capture bags.

The sample collected from the worker's breathing zone (outside the worker's dust mask) was evaluated at an exposure level of 5.38 mg/m3 of wood dust on an 8-hour TWA basis. The proposed PEL for wood dust (hard and soft wood) is 5 mg/m3 TWA8. This worker was potentially overexposed to wood dust concentrations above those specified by the proposed standard, but the dust mask provided protection from the inhalation of the wood dust and was considered sufficient for compliance

with the proposed standard.

Roadwork and Pipelines. Construction workers face many potential exposures during activities associated with roadwork and pipelines. These include asphalt laying, blasting and excavation,

pipe wrapping, rock crushing, water well drilling, traffic line painting, and cable laying.

Asphalt laying involves the application of asphalt mixtures to traffic bearing surfaces such as roads and parking lots. The asphalt is normally dispensed from pavers at temperatures ranging from 200°F to 350°F. Some paver models can lay pavement that is more than 20 feet wide. The number of workers may vary from four to seven per paver. After the asphalt is placed, it is smoothed by a rolling machine. If the edges along curbs cannot be rolled, then they must be tamped manually. Associated with the laying of asphalt is the application of the tack coat. This asphalt emulsion must be sprayed on all the edges where an asphalt joint occurs. On those jobs where only a new layer of asphalt will be applied, an asphalt tank truck can be used to apply the tack coat. For joints and curbs, a worker can apply the tack coat from an oil pot equipped with a sprayer. Workers engaged in all of the functions associated with asphalt traffic surface construction are likely to incur exposure to asphalt fume.

Operators of paving equipment have the potential to be exposed to asphalt fumes. Enclosure in a plexiglass cab with a supplied air system that filters out asphalt fumes would control the operator's exposure. Workers immediately adjacent to the paving operation would have the greatest likelihood of exposure after the paving machine operator. If exposures are above the proposed PELs, these workers would be required to use a NIOSH approved air purifying respirator to

control exposures.

CONSAD evaluated worker exposure to asphalt fumes during the paving of an airport runway near Pittsburgh, Pennsylvania in August, 1990 [2; Firm 33]. The paving operation crew consisted of nine people. An asphalt paver and vibrating roller were used to settle and roll the asphalt surface. The asphalt was delivered to the site by trucks and fed into the paver. Inside the paver, the asphalt is heated to about 300°F. The asphalt was dispensed from the paving machine onto the work area. The paver was operated by one worker, while two others made leveling adjustments to the machine. The remainder of the crew followed behind the paver to level, roll, and finish the paved material. The paving work was done in a large open area, and a variable breeze was present throughout the shift.

Four workers were evaluated for their exposure to asphalt fume (benzene soluble portions) during the sample period of six hours. These four workers

consisted of the paver operator, the two paver adjusters, and a follow-up worker. The lab results of the samples obtained showed that all of the airborne concentrations of asphalt fume (benzene soluble) for the sampling period were less than 0.09 mg/m3.

Workers engaged in blasting and the excavation of tunnels are assumed to have a potential for exposure to particulate matter (total dust) following the blast and also to the off-gases generated by the explosives. Excavation done by earth movers will also be a source of exposure to total dust for the workers in the area. Additionally, the exhaust from excavation equipment in tunnel areas may expose workers to elevated levels of carbon monoxide, carbon dioxide, and nitrogen dioxide.

Exposures to total dust above the proposed PEL can be controlled with disposable dust masks. While the offgases generated by explosives and the particulate matter generated during excavation or blasting processes may result in worker exposures, it is likely that these exposures are within corresponding PEL's due to the distance that workers would be located away from the immediate point of operation. However, the use of earth moving equipment in confined areas could result in overexposures to carbon monoxide. Portable exhaust and fresh air supply systems should be used to provide fresh air into the work zone. In addition, constant monitoring for carbon monoxide should be conducted anytime gas or diesel powered heavy equipment is used in a confined area.

Workers engaged in the handling and preparation of charges for blasting may be exposed to the components of the explosive. However, it is believed that these exposures are not significant due to their short duration.

Workers engaged in earthmoving and trench excavation operate large-scale earthmoving equipment. The sources of exposure to these workers include particulate matter during the movement of dirt and natural gas containing hydrogen sulfide that may be present beneath and around trenches. Water spraying can be used to reduce exposures in some applications, but workers will generally need to rely on respiratory protection if potential exposures exceed the proposed PELs.

Wrapping pipes with asphalt wrapping material is done in underground piping installation. Asphalt is used as a pipe wrapping joint sealant and adhesive. Exposures to asphalt fume arise in both the heating process that liquifies the material and in the

application of the material to the pipe wrapping.

Because this work activity may occur over vast areas (several miles of pipeline), exhaust ventilation may not be feasible to prevent exposure to asphalt fume. Therefore, respirators may be relied upon to prevent inhalation of airborne contaminants when concentrations exceed the PEL. A disposable respirator with NIOSH approval for organic vapors would provide adequate protection in most work situations involving this activity.

Rock drilling and water well drilling activities present potential exposures to airborne substances. A NIOSH Health Hazard Evaluation of water well drillers [18] was conducted to assess exposures to PVC cement used in the installation of well casing and water well pipe. (There was no indication in the report that there were any potential exposure problems from the drilling activity itself.) All of the firms involved in the study used a cement which contained tetrahydrofuran, cyclohexanone, and PVC resin.

The well drillers' exposure to tetrahydrofuran and cyclohexanone was determined from four breathing zone samples. The tetrahydrofuran exposure from one 20 minute sample was at a level of 20 ppm. Given that there was no other exposure during the rest of the shift, this was considered as a full day's exposure of less than an 8-hour TWA of 1 ppm. Tetrahydrofuran was not detected in any of the remaining samples. Cyclohexanone was not detected in any of the samples.

Workers may be exposed to various dusts during drilling activities. The nature of the dust is dependent upon the geologic structure where the work is conducted. The airborne concentration of dust is affected by the moisture content of the soil, weather conditions, and work practices. Where potentially high airborne dust concentrations exist, worker exposures can be reduced through the use of a water spray. The water spray can act to suppress dust in worker breathing zones. Where the exposure cannot be adequately controlled through the use of a water spray, a single use or disposable particulate respirator could provide adequate protection to prevent inhalation of dust.

Exposures may be a concern during the spray painting of traffic lines for both large and small projects. For large projects, such as roadways, a tank truck is generally employed with the sprayer mounted at the rear. For smaller projects, such as parking lots, a hand held compressed air sprayer or a

manual compressed air liner may be used.

On roadway projects, workers who follow the spray truck placing barriers to protect the freshly painted lines may be exposed to paint solvents, lead, or chromates. For manual operations, exposures may take place at any time during the application process.

The potential for overexposure to solvent vapors and metal pigments in the paint is unlikely. Most of this work occurs outdoors with natural ventilation. If an overexposure potential exists, it would be controllable through the use of an approved half-mask air-purifying respirator.

The installation or service of water pumps or pipelines and the handling and manipulation of water service piping does not present any apparent chemical exposures. However, there may be a potential for exposure to chlorine during the preparation and treatment of the water prior to service activation.

If an exposure to chlorine occurs, it would most likely be of short duration; OSHA is proposing a short-term exposure limit for such situations. To prevent overexposure to brief high concentrations of chlorine, a full-face respirator would be required. This is necessary because chlorine is a potent irritant of the eyes and respiratory tract. Implementation of engineering controls does not seem practical due to the unpredictability of the frequency of exposure, duration of exposure, or airborne concentration which may be encountered.

Cable plowing involves the formation of a trench for the laying of cable broadcast and telephone cable lines. The trench is created by mechanical means and the cable is unrolled into it from a spool. Workers associated with the process of digging the trench have the potential for exposure to particulates generated.

The likelihood of overexposure to dust generated during formation of cable trenches is considered remote. Engineering controls do not appear practical and therefore controls would be limited to respiratory protective equipment. For moderate exposures, disposable dust masks would be appropriate with potential up-grade to half-mask respirators should exposures become severely elevated.

Asphalt or concrete road milling is done during road reconstruction projects. During the process, mechanical equipment is used to remove several inches of road surface while maintaining the road base. The mechanical action of the road milling machine on the road surface generates and disperses particulate matter. The machine

operator and nearby workers are exposed to the dust produced.

The machine operator, facing the highest exposure, can be enclosed in a ventilated cab and isolated from the dust. A continuous water spray and wetting operation can also be maintained. If the wet spray does not achieve adequate suppression, then the use of disposable dust respirators would provide additional protection for members of the work crew.

Rock crushing activities are typically set-up as stationary units in close proximity to the area that the rock removal is taking place. The rocky material is collected and unloaded into the crusher. The rock crushing operation is an inherently dust-generating operation that affects equipment operators and ground workers. Exposures to respirable silica quartz and other respirable dusts occur.

Water sprays that are applied at the point of dust generation provide an inexpensive means of reducing employee exposure to airborne dust. Engineering controls consisting of an air ventilation system can be used to protect equipment operators; plexiglass enclosures with supplied-air ventilation are recommended. In addition to wetting operations, appropriate disposable dust respirators are recommended to protect ground workers.

The practice of spraying oil on gravel road surfaces is conducted to minimize dust generation. The operators of these spray trucks have the potential for airborne exposure to oil mist (mineral oil) that is generated during the atomization process. The likelihood of an overexposure to oil mist is considered remote due to the fact that the area with the highest elevated concentration of oil mist is near the rear of the vehicle, and the operator is typically driving away from the point of application. Furthermore, the vehicles typically have enclosed cabs which effectively isolate the operators.

Spreading gravel for roadbeds and other purposes may also cause some exposures. Road building requires the use of a substantial amount of gravel. The gravel is used as a base for the road surface. As a consequence of the amount of material involved, the gravel is normally delivered to the work site in 20 ton dump trucks. In the process of unloading the gravel, workers that are in close proximity to the operation are potentially affected by the dust

Keeping workers a reasonable distance away from the dumping operation is likely to control most worker exposures during this activity.

generated.

However, gravel with a high small-particle content could be sprayed with water prior to dumping and spreading to control dust generation. Since most of the delivery vehicles (dump trucks) are equipped with enclosed cabs, the drivers' exposures are likely to be within acceptable limits. Enclosure of the equipment operators spreading the gravel, in plexiglass-enclosed cabs with supplied-air ventilation systems which filter out particulate matter, could be used where water spray techniques fail to adequately control extremely high dust levels.

Miscellaneous Activities. Workers that are engaged in the fueling of construction service vehicles and equipment that operate on gasoline, diesel fuel or propane are likely to be exposed to these fuels. There may also be additional exposure to the combustion products associated with these fuels. It is believed, however, that these exposures will generally be insignificant.

The primary hazard posed by fuels is fire and explosion. Because of this potentially catastrophic danger, fuels should be handled with care. Proper storage, handling and transport of fuel is extremely important. If workers follow proper fuel handling practices, only minor exposures to fuel vapors and gases should occur. Also, this activity typically occurs outdoors where natural dilution ventilation occurs.

Joining pipes with joint compounds is a manual activity that occurs with the use of plastic pipe. The activity is normally carried out by applying the joint sealing compound with a fibrous applicator or brush to the joints to be mated. Worker exposure occurs from a number of organic solvents that may be contained in the sealant.

This activity usually occurs in situations in which it is difficult to implement engineering control measures. The activity is usually intermittent and involves crews of one or two employees who are mobile throughout the day. If a potential overexposure to a solvent vapor or metal fume would occur, the use of a respirator would be the required protection measure.

Some joint compounds contain organic solvents for which OSHA is proposing a skin designation. Two such substances include cyclohexanone and methyl alcohol. A natural rubber glove would provide adequate protection against skin contact from both substances while conducting this activity.

A field survey of exposure to organic solvents during the installation of plastic pipe was conducted by NIOSH in the

San Francisco, California area in 1983 [19]. Six of the breathing zone samples taken were at least five hours in duration. These samples were tested for methyl ethyl ketone (MEK). tetrahydrofuran (THF), dimethylformamide (DMF) and cyclohexanone solvents of plastic pipe adhesives and cleaners. The work performed by the plumbers and pipefitters included installing plating line pipe, laying 3", 4" and 6" PVC pipe in a ditch, installing PVC pipe in a sewage treatment building, and setting bathroom, kitchen and bar sink traps in a residence. All exposures were below the corresponding proposed PELs.

NIOSH also conducted a health hazard evaluation of plumbers in the Boston area in 1981 to assess the health effects from working with PVC pipe cements and cleaners [20]. Personal samples were taken from one plumber at one housing development and from seven plumbers at another housing project. The samples were analyzed for MEK (methyl ethyl ketone), THF (tetrahydrofuran) and Cyclohexanone. The results reported showed TWA exposures below proposed limits. Combined equivalent exposure for one of the eight plumbers exceeded unity. NIOSH recommended that air concentrations of PVC cements and cleaners be reduced by increasing natural room ventilation in open spaces and by providing local exhaust ventilation in closed or semi-confined spaces. NIOSH also stated that wearing a well fitted, well maintained respirator should provide a sufficient factor of protection.

The joining of plastic electrical conduits is a manual activity similar to the joining of plastic pipes. The ends of the conduit to be joined are coated with an adhesive by brush or lid applicator and mated. The organic solvents contained in the adhesive create the exposure hazard. For the solvents encountered during this activity, organic vapor cartridge half-mask respirators would provide adequate protection. Two commonly used solvents in this activity also appear on the list of substances for which OSHA is proposing a skin designation. These substances are nbutyl alcohol and cyclohexanone. A natural rubber glove would provide adequate protection when handling compounds containing these substances.

The demolition of plaster walls is usually performed by applying a sledge hammer or similar tool to the wall with force. The break-up of the wall will generate particulate matter that will be dispersed into the immediate environment. Exposures encountered will consist of plaster of paris (calcium

sulfate) and total dust (particulates not otherwise regulated).

Demolition work is inherently a very dusty operation. Because the structure is being removed, exhaust units may not be practical. In most situations, a portion of the work crew would be expected to wear respiratory protection. A single use or disposable dust mask would generally be adequate. To reduce the total number of workers requiring respiratory protection, partitions or screens could be set-up to isolate the demolition area. Also, a water spray and wet sweeping practices would help to suppress dust in worker breathing zones.

CONSAD surveyed the environmental exposures associated with a kitchen demolition project in Pittsburgh, Pennsylvania in June, 1990 [2; Firm 28]. Two workers were involved in a teardown of the wall under observation. These men used a crowbar and a reciprocating saw to remove bricks, ceramic tile, plaster, tar paper and wood materials. The workers were monitored for their exposure to total dust. The TWA exposures to total dust during the sampling period of about five hours were determined to be 1.87 mg/m3 and 3.89 mg/m3. Exposures during the remainder of the shift were minimal. Personal protective equipment was employed that included cartridge respirators, safety glasses, steel-toed shoes and cotton gloves.

Torquing galvanized bolts is done by ironworkers during the erection of structural steel. The use of impact wrenches to torque galvanized bolts causes zinc oxide dust to be generated and dispersed into the worker's breathing zone. The likelihood of exposures above the proposed PEL is considered remote. This activity usually occurs outdoors, involving small mobile crews in situations where it is difficult to implement engineering control measures. If an overexposure problem to zinc oxide dust exists, a disposable particulate respirator with appropriate NIOSH approval would provide adequate protection.

Airborne exposures to carbon monoxide, carbon dioxide and nitrogen dioxide fumes generated by gasoline and diesel fuel powered machinery may become problematical when the equipment is operated indoors. Mobile cranes (cherry pickers), man lifts, and portable cutting tools are examples of the kinds of powered equipment that could be used for indoor construction work. Therefore, precautions should be taken to assure that fresh air is provided and that the entire area is ventilated.

To control the build-up of carbon. monoxide, carbon dioxide and nitrogen dioxide generated by portable machinery operated indoors, blowers should be used to provide fresh air to the work area to dilute the combustion gas by-products. In most situations, worker exposures can be controlled with fresh air controls. Where space heaters are used in work areas, attempts should be made to vent the emissions directly outside. This will prevent the release of gaseous by-products in the work area. If this cannot be done, then provisions should be established to supply fresh air.

The heat fusion of plastic pipes and conduits is a technique used for joining purposes. In this method, a device similar to a curling iron is used to heat the plastic material to 180–200 degrees fahrenheit. At these temperatures, the pipe joint can be fused. This method is believed to only be used in polyethylene pipe installations and it is reported that no measurable quantities of gases or vapors are emitted during the process.

Repair and cleaning activities in sewer systems may involve the physical removal of material from occluded sewer lines and also the possible repair of damaged pipes. Material removal and/or repair may require that employees enter the sewer system. Employees engaged in this work may have the potential for exposure to ammonia, carbon dioxide, methane, and

hydrogen sulfide.

Worker exposures to the chemicals used in cleaning sewer systems are often exacerbated by the fact that the work is being done in a confined space. Additional hazards of confined spaces include oxygen deficient atmospheres and/or atmospheres with hazardous levels of methane or hydrogen sulfide. Exposure monitoring should be conducted prior to and during all work activities involving a confined space. Fresh air should be supplied to the confined area at all times to reduce the health and explosion hazards, and workers should wear supplied-air respirators if exposures are potentially in excess of allowable limits.

Conclusion. OSHA has preliminarily concluded that compliance with the proposed PELs is feasible in the construction industry. Respirator use may be necessary in some high-exposure situations, but the overall need for respiratory protection in the industry should remain relatively low. Standard engineering controls and work practices designed for dust suppression and the dilution of fumes can be applied effectively to many activities. An important factor in providing workers with adequate health protection is the

awareness of the presence of potentially hazardous substances.

6. Costs of Compliance

The total annual cost of compliance with the proposed regulation of airborne contaminants in the construction industry (with a PEL of 5 mg/m³ for asphalt fume) is estimated to be approximately \$94 million for all firms affected by the rule. With alternative PELs for asphalt fume of 0.5 mg/m³ or 0.2 mg/m³, the annual cost would increase by an estimated \$25 million or \$51 million, respectively.

Methodology. The costs of compliance were estimated for individual activities in each SIC group. For each activity, the potential for hazard exposure was estimated based on data from a variety of sources. CONSAD Research Corporation conducted a survey of the construction industry for this purpose. Survey responses by construction establishments described the circumstances in which the activities took place, how the work was done, and the nature and extent of existing hazard abatement controls in place. Establishments identified hazardous substances used and the products where they were found. The chemical components of specific products were identified by referencing material safety data sheets (MSDSs). The survey responses also provided information on the numbers of employees involved in activities, the frequency and length of exposures during the activities, and the number of days the activities took place In addition, the survey supplied data on the use of specific engineering controls. work practices, and personal protective equipment by work activity, currently in

place across a representative sample survey of all job sites nationwide.

Survey data was supplemented with detailed descriptions of activities in NIOSH studies. Further information on construction activities was collected by CONSAD through a series of site visits. Exposure monitoring data were collected during site visits, from NIOSH studies, from investigations by state health departments, and from OSHA's IMIS database. Monitoring results from the IMIS database were linked to specific circumstances and activities by reviewing information from the inspection reports (form 91a) in OSHA area offices.

The activity-based approach used to determine exposures and the need for additional controls allowed for explicit consideration of mixed exposures. Exposures to multiple substances were evaluated according to the formula in the proposed regulation; combined exposures exceeding unity were considered to be exposures above the proposed PELs. As a result, the costing methodology included allowances for meeting the mixed exposure limit (MEL) as well as individual PELs.

Once the nature and extent of potential substance exposure was determined for a specific activity and SIC group, the costs of the controls necessary for compliance with the proposed PELs was assessed. The control hierarchy prescribed by OSHA requires that engineering and work practice controls be implemented when feasible. Engineering controls are widely available and effective for controlling exposures during many construction activities.

The most common type of engineering control involves increased ventilation. Depending on the application, this can be accomplished with a fan, a fresh air supply blower, or a portable exhaust hood. Unit costs for this equipment range from under \$300 for a fan to over

\$1,500 for a portable exhaust ventilation unit.

Physical isolation of workers from the exposure source is another method of engineering control. Screens and partitions could cost an estimated \$240 on affected projects; total enclosure of a worker in a plexiglass cab would have a cost of up to \$4,000.

Equipment mounted dust catchers, vacuum cleaning, and water spraying devices are relatively inexpensive control methods that are applicable in many situations. The insulation of pipes (to keep asphalt kettles at lower temperatures) and the use of vapor control nozzles are additional examples of adapting engineering controls to construction activities. A description of the applicable controls for each activity is presented in the section on technological feasibility.

The annualized cost of engineering controls was derived by spreading the unit cost over the average useful life of the equipment and including an annual cost of capital of 10 percent. Annual and recurring costs associated with the use of controls were added to the annualized cost of controls to obtain the total annual cost to establishments of providing the controls.

Substances for which OSHA is adding a skin designation to the PEL should be controlled for dermal exposure. Different types of gloves are available to adequately prevent skin contact with different types of substances. Costs for gloves range from \$1.80 per pair for cotton gloves to over \$4.00 per pair for butyl rubber gloves. Barrier skin cream is also effective in some applications and is estimated to cost less than \$10 per worker per project.

In the event that feasible engineering controls and work practices are insufficient for reducing exposures below the proposed levels, respiratory protection is necessary. Disposable dust masks are available for about \$1.60 each while a powered air purifying respirator

may cost as much as \$570. Various respirators with intermediate levels of protection range in cost from \$8.00 for a disposable metal fume mask to \$165 for a full mask respirator. The replacement of cartridges for full-and half-mask respirators is estimated to cost \$8.00.

The costs of compliance for specific activities in the affected SIC groups were aggregated to national estimates by using a computer model with standard statistical extrapolation techniques for representative sampling. The survey responses provided information on the value of work done, the value of the whole project, the duration of the project, the percent of time devoted to a particular activity, the total number of workers involved, and the total worker-hours of exposure. Within each survey cell, these numbers were compared to aggregate figures published by the Department of Commerce, such as total numbers of employees by size of establishment and SIC code, and total values for categories of projects and types of contruction work done. Sample data were then multiplied by appropriate weighting factors to project the sample up to nationwide "universe" estimates of the variables being measured. For a detailed explanation of this methodology, see CONSAD Report "Economic Analysis of Proposed Changes to Airborne Contaminant Standards for the Construction Industry" with Appendices, April 1, 1991 [1].

Breakdown of Costs. The total estimated annual costs of compliance, \$93.9 million, are presented in three different ways. Table V-B10 presents the costs for construction establishments in each SIC group; Table V-B11 presents the costs of compliance for specific types of activities; and Table V-B12 presents the estimated costs by the type of control methods and protective equipment necessary for compliance.

Source: Office of Regulatory Analysis, OSHA, Department of Labor; based on CONSAD Research [1].

Establishments in SIC 1721, Painting and Paper Hanging, would have estimated total annual compliance costs of \$21.2 million. Over half of these costs are expected to be for exterior painting of wood and masonry finishes. These activities may involve potential exposures above the proposed PELs for petroleum distillates and silica. A variety of other chemicals would also be present, including ethylene glycol, propylene glycol, ethyl benzene, xylene, titanium dioxide, and others. Interior

painting of walls, ceilings, and metal substrates would account for an estimated \$4.2 million in compliance costs. The relatively low estimated compliance costs associated with these activities reflect the current widespread use of protective measures already provided for workers involved in these activities. Employees may encounter potential exposures to a long list of chemicals. In addition to those specified above, airborne contaminants may include ammonia, butoxyethanol, organic and inorganic mercury compounds, methyl alcohol, 2-butanone, lead, chromates, toluene, and others.

The estimated annual compliance costs for SIC 1799 are \$17.6 million. This SIC group includes miscellaneous special trade contractors not elsewhere classified. Establishments in this group may be involved in antenna installation, caulking, preparing forms for poured concrete, ornamental metal work, waterproofing, epoxy application, grave excavation, lead burning, paint stripping, sandblasting, swimming pool construction, welding, fence construction, and other specialized services. Over half of the estimated compliance costs are attributable to activities that entail burning, cutting, or welding on painted surfaces resulting in potential exposures above the proposed PELs for lead, nickel, and zinc oxide fume. Additional protection for employees would also be necessary for grinding, drilling or cutting painted surfaces, application of waterproofing, batch mixing of concrete, earthmoving. abrasive blasting, and several other activities. Employees in SIC 1799 may be exposed to dozens of substances. Substances for which potential exposures above the proposed PELs are most prevalent include silica, portland cement, lead, welding fume, butoxyethanol, ethyl benzene, methyl

chloroform, ethylene glycol, petroleum distillates, titanium dioxide, and xylene.

SIC 1542 is comprised of general contractors for buildings other than residential or industrial buildings. Total estimated annual compliance costs for these establishments are \$10.4 million. Employees of these general contractors are engaged in a wide variety of activities which may involve potential exposures above the proposed PELs. Protection of employees during sealing and coating operations accounts for an estimated \$8.8 million of the total costs for this SIC group. The primary hazards identified during this activity are exposures to petroleum distillates, toluene, and xylene.

Establishments in SIC 1741, masonry and stone work, would have estimated annual compliance costs of \$5.8 million. These costs are primarily attributable to providing additional protection to employees from exposure to portland cement and silica during batch mixing of

mortar and cement.

Firms engaged in plastering, drywall, and insulation work (SIC 1742) would have estimated total annual compliance costs of \$5.7 million. Activities for which additional protection would be necessary include application of fireproofing, insulation installation, burning, cutting and welding on painted surfaces, interior painting, and batch mixing of mortar and cement. Workers may experience potential overexposures to lead, mercury, and ethylene glycol.

Annual compliance costs for structural steel erection (SIC 1791) are estimated at \$5.1 million. Activities of concern include welding, cutting, grinding and drilling, especially when conducted on painted surfaces. Substances for which overexposures may occur include lead and welding

fume.

The estimated annual cost of compliance for SIC 1611, Highway and Street Construction, would be \$5.1 million. Most of these costs are attributable to abrasive blasting activities. Employees would primarily be provided with additional protection from silica exposures as necessary.

The proposed PEL for asphalt fume of 5 mg/m³ is not expected to involve significant additional costs for establishments involved in highway and street construction. However, establishments in this SIC group would face significantly larger compliance costs under alternative PELs for asphalt fume of 0.5 mg/m3 or 0.2 mg/m3, and OSHA estimated the potential costs associated with the lower PELs for these establishments.

The primary activities of concern would be paving and black topping.

About 240,000 employees are involved in cartridges). With a PEL of 0.5 mg/m3 this type of work, representing about 160,000 full-time equivalent (FTE) workers. This figure was adjusted downward by 40 percent to account for days or shifts of work without direct and prolonged exposure to hot asphalt. For example, workers involved in site preparation and breakdown, traffic control, truck driving, and other activities would not experience the levels of exposure typically attributed to paving work. Thus, about 144,000 employees or 96,000 FTE workers are considered to have exposure to asphalt fume during paving operations.

Exposure monitoring data for these activities was submitted to NIOSH in response to a request for information published in July, 1990. The National Asphalt Pavement Association (NAPA) found that full-shift time-weighted average (TWA8) exposures for paving workers ranged from 0.10 mg/m3 to 0.76 mg/m3 with a mean of 0.21 mg/m3 (benzene-soluble fraction) [2]. The Asphalt Institute cited data in their submission indicating that the mean TWA8 exposures for paving workers was 0.33 mg/m3, and also included summary data from dozens of studies published by NIOSH and other authors. For example, Virtamo et al (1984) reported to have found mean exposure levels of 1.2 mg/m3, with a range of 0.1 mg/m3 to 2.7 mg/m3, among one group of paving workers [3]. The Minnesota Department of Transportation reported that worker exposures during asphalt crack filling in 1990 averaged 0.89 mg/ m3, with a range of 0.30 mg/m3 to 1.29 mg/m3 [4]. CONSAD reported that during a site visit to an asphalt runway paving operation worker exposures averaged less than 0.1 mg/m3 [1]. A report prepared for the Asphalt Institute by Radian Corporation found exposures during paving ranging from less than 0.1 mg/m³ to 5 mg/m³, with a geometric mean of 0.29 mg/m³ and an arithmetic mean of 0.57 mg/m3 [6]. All monitoring results represent the benzene-soluble fraction of asphalt fume.

Appropriate work practices and control of the temperature of the asphalt can help minimize employee exposures. Engineering controls should be used to reduce exposures before resorting to respiratory protection. Due to the nature of paving operations, the prospects for achieving significant reductions in exposures by these means appear to be limited. OSHA estimates that 50,000 FTE workers (about half of the exposed workforce) would be exposed above the proposed PEL of 0.2 mg/m3 and would be required to wear respiratory protection (such as a half-mask respirator with organic vapor

this number would be about 10,000 FTF workers. Depending on the extent of rotation among jobs, these figures represent from 100,000 to 200,000 employees wearing respirators for some time each year.

For purposes of estimating the cost of complying with the proposed PEL of 0.2 mg/m3, it is assumed that 100,000 respirators would be purchased for \$22 each. With an average life span of five years, the annualized cost would be about \$580,000. In addition, the respirator cartridges would need to be replaced on average for 50,000 workers every four days at a cost of \$8 per set. This would amount to an annual cost of \$26 million (260 work days per year divided by 4, multiplied by \$8 and by 50,000 workers). Providing protection from asphalt exposure with a PEL of 0.2 mg/m3 thus would account for about \$26.6 million in compliance costs for establishments in SIC 1611.

With a PEL of 0.5 mg/m3, it is assumed that 50,000 respirators would be purchased, and that cartridges would be replaced on average for 10,000 workers every four days. Protection from asphalt exposure would thus account for \$5.5 million in total compliance costs for SIC 1611.

Total annual compliance costs for establishments in SIC 1761, Roofing, Siding, and Sheet Metal Work, are estimated to be \$2.2 million with a PEL for asphalt fume of 5 mg/m3. Most of these costs would be incurred for activities involving grinding, drilling, or cutting painted surfaces and for the application of roofing systems. Employees may potentially be exposed to lead, fibrous glass, and asphalt fumes.

Estimated compliance costs for establishments in SIC 1761 would be significantly higher under alternative PELs for asphalt fume. OSHA estimated the compliance costs that would be associated with PELs for asphalt fume of

0.5 mg/m3 and 0.2 mg/m3.

The Asphalt Institute cited data in their submission to NIOSH indicating that the mean TWA8 exposures for asphalt roofing workers was 0.80 mg/ m3, and also included summary data from dozens of studies published by NIOSH and other authors. For example, Brandt et al (1985) is reported to have found mean exposure levels of 3.30 mg/ m3, with a range of 1.40 mg/m3 to 7.80 mg/m3, among one group of roofers [3]. Exposure monitoring data from four NIOSH studies show mean exposure levels (and ranges of exposures) among roofers of 0.54 mg/m³ (0.11 mg/m³-1.89 mg/m³), 1.07 mg/m³ (0.90 mg/m³-1.20 mg/m³), 0.83 mg/m³ (0.35 mg/m³-2.10

mg/m³), and 0.71 mg/m³ (0.30 mg/m³–1.30 mg/m³) [3]. Radian Corporation found exposures during asphalt roofing ranging from less than 0.1 mg/m² to 2.5 mg/m³, with a geometric mean of 0.28 mg/m² and an arithmetic mean of 0.52

mg/m³ [6].

The Bureau of Labor Statistics reports that there are over 210,000 roofers in the United States [5]; these employees represent about 140,000 full-time equivalent workers. According to the 1990/1991 market survey conducted by the National Roofing Contractors Association, asphalt roofing comprises about 35 percent of roofing work, which would represent about 49,000 FTE workers. Some employees in these operations may not need respiratory protection; employers may have to make a determination of need before each shift.

For purposes of estimating the costs associated with this proposed rulemaking, the number of workers engaged in asphalt roofing was adjusted downward by 30 percent to account for days and shifts that do not involve significant exposure to asphalt fume. For example, roofing jobs typically include time for removing old roofs, transporting and setting up equipment, and other activities without direct exposure to asphalt fume. Thus, about 34,000 FTE workers are estimated to be working with hot asphalt in roofing jobs.

Asphalt exposures during roofing can be minimized through the use of appropriate work practices and by carefully controlling the temperature of the asphalt. The asphalt in the kettle can be kept at lower temperatures if the pipes transporting the asphalt to the point of use are insulated. Improvements in these areas and the use of other engineering controls should be made prior to reliance on respiratory protection and may help keep some exposures below the proposed PEL. However, the available monitoring data indicate that exposures for most roofers working with asphalt are likely to be above 0.2 mg/m3 even after engineering control and work practice modifications are made. OSHA estimates that 30,000 FTE workers, representing 50,000 to 80,000 employees, would be required to wear respirators with a PEL of 0.2 mg/

With a PEL of 0.5 mg/m³ about 25,000 FTE workers would be exposed above the PEL during asphalt roofing, and about 20,000 FTE workers would be required to wear respirators.

Based on the results of the construction survey, approximately 1,000 establishments would need to insulate their asphalt-carrying pipes. The unit cost would be about \$150 with

a life span of one year. The total cost to the industry of installing additional insulation on pipes would be \$150,000.

A half-mask respirator with organic vapor cartridges would provide adequate protection from asphalt fumes. The cost of each respirator would be about \$22 and a set of replacement cartridges would cost about \$8 [1]. Cartridges would need to be replaced every 4 days on average. With a life expectancy of five years, respirators purchased for 60,000 employees would have an annualized cost of about \$350,000. The replacement of cartridges every four days for an average of 30,000 employees would have an annual cost of about \$15.6 million. Providing protection from asphalt exposure during asphalt roofing with a PEL of 0.2 mg/m2 would thus account for an estimated \$18.1 million in compliance costs for establishments in this SIC code.

With a PEL of 0.5 mg/m³, costs for insulating pipes and purchasing respirators would be about the same, and replacement of cartridges would have an annual cost of \$10.4 million. Protection from asphalt exposure during asphalt roofing with a PEL of 0.5 mg/m² would thus account for an estimated \$10.9 million in compliance costs for

establishments in SIC 1761.

Other SIC groups each have estimated compliance costs of less than \$4 million each. These costs are spread over various activities for which the potential need for employee protection is already recognized to some degree. The estimated compliance costs for many activities may include costs that would have to be incurred to meet existing PELs.

Based on the survey results, activities with the highest total compliance costs across all SIC groups would be burning, cutting, or welding on painted surfaces (\$19.6 million), exterior painting (\$15.1 million), concrete sealing and coating (\$10.1 million), and batch mixing of mortar and cement (\$8.3 million). Other activities with significant compliance costs include abrasive blasting, trench excavation, grinding and drilling on painted surfaces, interior painting, sanding, and welding and cutting steel.

Almost \$30 million of the total compliance costs would be used to provide engineering controls such as equipment-mounted dust catchers, portable exhaust hoods, fresh air supply blowers, enclosures, and water sprayers. The largest portion of costs, when examined by the type of control used, is for respiratory protection at an estimated annual cost of \$54 million. Work practices (e.g. the use of dust suppressants), personal protective equipment such as gloves and welding

masks, and administrative controls that include personal constant exposure monitoring, are additional measures that reduce potential risks to employees.

7. Economic Impacts

This section examines the economic impacts associated with OSHA's proposed revisions to the PELs in the construction industry. The overall impact of compliance with the proposed rule is not expected to be a substantial burden for the industry and is considered economically feasible for each sector.

The economic impacts were evaluated by comparing the cost estimates presented in the previous chapter with economic and financial statistics available for the construction industry. These data were combined with an economic analysis of the structure of the industry and the affected markets to determine the likely effects. The economic impacts were assessed for each 4-digit SIC group by type of construction project.

Table V-B13 shows the estimated costs of compliance as a percent of the net value of construction for each SIC group. For the industry as a whole, total costs of compliance are estimated to be less than one thirtieth of one percent of the total net value of construction. For each of the SIC groups, compliance costs would represent less than 0.3 percent of the respective value of construction.

Table V-B14 presents data for each of the SIC groups on the number of employees, the number of establishments, the total annual payroll, the average annual payroll per establishment, the average cost of compliance per firm, and the average

cost of compliance per employee. The average annual payroll per establishment in the construction industry is about \$150,000. The average estimated cost of compliance per firm would be approximately \$175, and the average cost of compliance per employee would be less than \$24.

The estimated costs of compliance are compared to the value of construction by the type of construction project in Table V-B15. For each type of construction project the compliance cost would represent less than one tenth of one percent of the total value of such construction. Compliance costs for both building and nonbuilding construction on average would represent less than 0.03 percent of the total value of such construction.

The SIC group with the highest ratio of estimated compliance costs to net value of construction is SIC 1721.

Painting and Paper Hanging. The need for and use of respirators and other methods of exposure control is already relatively widespread in this industry sector. Establishments in this SIC group are regularly engaged in activities involving airborne and dermal exposures to the substances in this proposed rulemaking. Activities include

interior and exterior painting (including bridge painting), abrasive blasting and other methods of surface preparation, and occasional soldering, brazing, grinding, and cutting. These activities expose workers to several hazardous substances, including ethylene glycol, toluene, xylene, petroleum distillates, mercury, and silica.

TABLE V-B15.—COMPLIANCE COSTS BY TYPE OF CONSTRUCTION

Source: Office of Regulatory Analysis, OSHA; based on U.S. Department of Commerce, 1987 Census of Construction, and CONSAD survey [1].

The compliance costs in this sector are primarily attributable to a minority of firms that do not implement the sound industrial hygiene practices followed by most firms. Many circumstances involving exposures above the proposed PEL also involve exposures above the existing PELs. The proposed rule codifies current consensus standards which have already been adopted by responsible employers.

The estimated average cost of compliance per establishment in SIC 1721 would be less than 1 percent of the average annual payroll per establishment or about \$150 per employee annually. Given the extent of protection currently provided in this

industry, the incremental costs necessary to achieve compliance with the proposed rule are relatively small. The rule would not require widespread changes in accepted practices; many firms with appropriate industrial hygiene practices would remain unaffected.

Estimated compliance costs for SIC 1799, Special Trade Contractors, Not Elsewhere Classified, are less than 0.18 percent of the value of construction for this sector. The group includes establishments engaged in paint removal, waterproofing, and miscellaneous construction work, resulting in worker exposures to lead and other chemicals. Many of these

workers are not adequately protected from exposures to hazardous substances. A lack of awareness of the presence and nature of potential health hazards may contribute to the problem.

The cost of providing protection would not be a significant burden for employers; the requirements associated with the proposed PELs are equivalent to those for the existing PELs in many activities. Responsible employers already provide the necessary protection for their employees. The average cost of compliance per firm represents less than 0.8 percent of the average payroll per firm.

With a PEL of 5 ug/m³ for asphalt fume, activities with potential asphalt exposure would largely be unaffected, and the impact of the proposed rule on paving and roofing establishments would be negligible. With a PEL of 0.2 mg/m3 for asphalt fume, employees engaged in asphalt roofing and paving work would probably be required to wear respirators routinely, and the resulting costs of compliance for establishments in SIC 1761 (roofing) and SIC 1611 (paving) would be significantly higher. As outlined below, the impacts of a standard with a PEL of 0.2 mg/m3 for asphalt fume would be nonnegligible but economically feasible for each of these industries.

With a PEL of 0.2 mg/m3 for asphalt fume, the estimated compliance costs for firms in SIC 1761, Roofing, Siding, and Sheet Metal Work, would represent about 0.15 percent of revenues. Increases in the cost of construction for these establishments primarily would result from the need to protect employees from exposure to asphalt fume. Most employees working with hot asphalt would be required to wear a

respirator.

The additional costs of providing employees with respiratory protection during asphalt roofing work would result in higher costs for completing this type of work. In addition to the costs of the respirators, some loss of productivity could be expected as employees wearing respirators are less able to perform strenuous work. The costs of supplying employees with respirators during a typical asphalt roofing job would represent about 1 percent of the revenues. The average productivity loss associated with wearing respirators may increase labor costs by 10 percent which would represent about 2 percent of revenues. The total estimated compliance costs to employers would thus be about 3 percent of revenues for asphalt roofing.

Routine use of respirators may potentially involve effects on productivity, safety, and health. In response to OSHA's recent Methods of Compliance proposal, several commenters expressed concern about such effects and the associated burdens for workers. Many statements generally supported the conclusion that "men often cannot sustain respiratory wear for the full shift." [Testimony of Morton Corn, May 30, 1990. See also statements by the United Steelworkers of America. July 10, 1990, by the AFL-CIO, October 3, 1989, and other comments in docket number H-160].

The impact of the increased costs would produce a combination of effects. Employers could attempt to raise prices

by about 3 percent to offset the compliance costs. The ability of

employers to raise prices sufficiently to cover all compliance costs would be limited, but a substantial part of the costs could be recouped. Employers engaged in asphalt roofing would probably experience a partial reduction in profits in conjunction with limited increases in prices to avoid losing business. Without any increase in prices, the estimated compliance costs would absorb about 60 percent of the average profits. Some marginal employers may decide to discontinue

asphalt roofing operations.

The total demand for asphalt roofing work would not be expected to change drastically as a result of a proposed standard for a PEL of 0.2 mg/m3 for asphalt fume. Adequate substitutes may not be available, and the increase in costs to building owners would not be unbearable. All employers in the country would be subject to the same requirements, and work in foreign countries cannot be substituted for projects in the United States. The inherent inelasticity of demand for asphalt roofing would ensure continued demand for such work. Total revenues and hours worked should not decline; establishments unable to continue asphalt roofing profitably would be replaced by more efficient firms. The proposed standard would be economically feasible for the industry as a whole.

With a PEL of 0.2 mg/m3 for asphalt fume, establishments in SIC 1611, Highway and Street Construction, would have the highest estimated cost of compliance per firm. This would partly be due to the relatively large number of employees per firm (22), and would partly be due to the extensive nature of the impacts in this sector. Over 80 percent of the estimated compliance costs would be associated with providing respiratory protection for employees working with hot asphalt. Apart from other potential effects of wearing respirators, the costs of providing protection as required by the proposed rule should be economically feasible for employers. The total costs would represent about one tenth of one percent of the revenues for this sector. the costs per establishment would be about 0.06 percent of the average payroll per establishment.

Other sectors and activities in the construction industry would be less affected by the proposed rule and the potential alternatives for the PEL for asphalt fume. The proposed changes in the PELs generally would not require drastic or widespread alterations in the nature of the work. The protection required by the standard would basically involve circumstances in

which potential health hazards are already recognized by many employers. To a significant extent the estimated costs of compliance reflect a lack of awareness by some employers or an insufficient application of all feasible controls in some activities. The incremental compliance cost for the proposed rule represents the increase in protection necessary to achieve more comprehensive protection for all employees. The feasibility of the proposed standard is evident since many employers conduct the relevant activities in compliance with the proposed requirements.

This proposed regulation would apply to all construction work done in the United States. While competition among domestic firms in the industry may be strong, the industry as a whole does not face significant competition from foreign contractors. Foreign contractors would also be subject to the requirements of the proposed rule for work done in this country. As a result, the costs of compliance are likely to be passed on in the form of higher prices for completed construction work. The expected increases for each type of construction project are small and are not expected to influence total demand for construction work. For example, the average costs of increased worker protection would add about \$40 to the cost of a new \$200,000 single-family house.

Reduced worker exposures to hazardous chemicals is likely to generally increase worker productivity and reduce the number of lost workdays due to illnesses. The lower costs associated with illnesses should result in an improvement in the overall efficiency of the construction industry.

Regulatory Flexibility Analysis. Pursuant to the Regulatory Flexibility Act of 1980 [Pub.L. 96-353, 94 Stat. 1164 (5 U.S.C. 60 et seq.)], OSHA has assessed the impact of the proposed standard on small businesses, defined as establishments with fewer than 20 employees. The impacts were evaluated for potential adverse impacts on small firms and their relative consequence compared with large firms.

In general, the costs of compliance for any firm will depend on the extent of worker exposures involved in the activities engaged in and on the extent to which workers are currently protected. The extent of worker exposure is directly related to the number of workers involved and the amount of work being done. For any given activity, work is likely to be done in a similar manner by both large and small firms, with costs proportional to

the scale of the project. Thus, it is estimated that the annual costs of compliance for any firm would also be proportional to the amount of work done over the course of a year.

Most of the compliance costs
associated with this rulemaking would
be incurred on a per employee basis. For
example, costs for disposable dust
masks can be estimated per employee
for each project and purchased as
needed. There is no evidence that small
firms would be put at a competitive
disadvantage as a result. Small firms
compete effectively with large firms for
all types of construction work and
outnumber large firms by a factor of
nine to one.

The size of the estimated compliance costs in relation to both payroll costs

and revenues suggests that any potential negative impacts would be negligible for both large and small size firms. OSHA concludes that the proposed regulation will not have an adverse impact on a substantial number of small entities.

Table V-B16 shows the number of small establishments and the average cost for small establishments. The average cost for small firms is approximately half of the average cost for all firms. Approximately 90 percent of all firms are small, and about 44 percent of the total costs of compliance would be borne by these establishments. The proposed standard would not create any differential between small and large firms in the cost of completing work, and thus no competitive disadvantage would be imposed on small firms.

Environmental Impacts. This proposed rule and its major alternatives have been reviewed in accordance with the requirements of the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321 et seq.), the Guidelines of the Council on Environmental Quality (40 CFR Parts 1500-1517), and OSHA's DOL NEPA Procedures (29 CFR Part 11). As a result of this review, OSHA has determined that the promulgation of this rule would have no significant environmental impact. Any changes that would result from compliance with this proposed rule would tend to reduce emissions of airborne contaminants from construction worksites.

TABLE V-B16.—ESTIMATED COSTS OF COMPLIANCE FOR SMALL AND LARGE FIRMS BY SIC CODE

SIC code	SIC description	Total number of establishments	Number of small establishments	Average cost for all establishments	Average cost for small establishments

C. Preliminary Regulatory Impact Analysis for Maritime

1. Introduction and Executive Summary

The proposed standard, extending the new Z-table PELs for general industry to the maritime industry, is examined in this report to estimate the costs, benefits, and economic impacts associated with the proposed rulemaking. In addition, a profile of the industry affected by the proposed standard is provided, along with a discussion of the regulatory and nonregulatory environment.

Industry Profile. An estimated 1,681 establishments will be affected by the proposed standard, 590 of which are in

SIC 3731 (Shipbuilding and Repairing) and 1,091 of which are in SIC 4491 (Marine Cargo Handling). Of a total employment of about 183,537 workers, 68 percent are employed in shipyards and 32 percent are in marine cargo handling.

Within shipyards, the proposed standard is expected to primarily affect welders and painters. In marine cargo handling, stevedores involved in RO-RO and forklift operations, as well as workers involved in various dry bulk operations, are expected to be primarily affected.

Employee Exposures and Benefits. Based on data obtained from OSHA's Integrated Management Information System (IMIS), a survey conducted for the general industry air contaminants rule, shipyard, marine terminal and longshoring studies, U.S. waterborne commerce data, and expert opinions, OSHA estimated that about 40,530 full-time equivalent workers are potentially exposed to substances affected by the proposed rule. Of these 40,530 potentially exposed workers, approximately 3,615 are estimated to be overexposed.

The overexposures in the shipbuilding and repairing industry result from welding and painting. In marine cargo handling, overexposures are likely to occur during RO-RO and break bulk forklift operations, as well as during the

loading and unloading of dry bulk cement.

OSHA estimates that an average of 245 total illnesses, of which 77 are lost workday cases, result from overexposures to substances affected by the proposed regulation. Of these illnesses, 196 total are expected to be avoided as a result of the proposed rulemaking, 62 of which are lost workday cases.

The proposed rule is also expected to reduce fatalities. Since long latency periods associated with occupationally related illnesses cause difficulty in diagnosing illnesses as being work related, fatalities resulting from such illnesses are difficult to determine. However, some substances covered by the proposed rulemaking to which workers are exposed are known to cause fatalities at levels above the

believes, that by reducing current PELs,

proposed PELs. OSHA therefore

an average of 1 to 2 fatalities per year will be avoided.

Nonregulatory Alternatives. OSHA believes that there are no nonregulatory alternatives that adequately protect most workers from the adverse health effects associated with exposure to the chemicals under consideration. OSHA believes that the tort liability laws and Workers' Compensation do not provide adequate worker protection due to market imperfections. Some employers have not complied with the standards recommended by professional organizations. The deleterious health effects resulting from continued high levels of exposure to hazardous substances require a regulatory solution, and the OSH Act requires the Agency to protect workers' health.

Technological Feasibility and Costs of Compliance. OSHA has determined that the standard is technologically feasible, as all of the provisions can be met by using currently available engineering controls and personal

protective equipment.

The proposed rule will require firms to incur costs for engineering controls necessary to bring overexposed workers to levels below the proposed PELs. The total annualized cost for firms to come into compliance with the proposed rule is estimated to be \$5,682,245. Of this amount, \$5,416,098 will be incurred by shipbuilding and repairing facilities to reduce welding and painting exposures. An estimated \$266,147 will be incurred annually by stevedoring establishments to reduce exposures to carbon monoxide and portland cement.

Economic Impacts and Regulatory Flexibility. The potential impact of

compliance on the industry was evaluated using estimated revenues and profits for each SIC group. The analysis revealed that even if compliance costs were fully absorbed by the industry (i.e., no pass through of costs to the consumer), neither profitability nor revenues will be significantly reduced. Costs as a percentage of revenues would not exceed 0.07; costs as a percentage of profits would not exceed 1.13 for either industry subsector.

Pursuant to the Regulatory Flexibility Act of 1980 (Pub. L. 96-353, 94 STAT. 1164 [5 U.S.C. 60 et seq.]), OSHA has assessed the impact of the proposed rule on small entities and concludes that there will be no significant effects on a substantial number of small firms. This act requires that in proposing new rules. federal regulatory agencies must examine their potential for imposing disproportionately heavier burdens on small businesses. Nearly 50 percent of the firms covered by the standard employ fewer than 20 employees and are defined as small. For the vast majority of these firms, it is anticipated that the economic impact of the standard will not be significant given the small magnitude of per worker compliance costs.

Other Effects. The proposed rule is not expected to have any significant effect on international trade because of the small magnitude of the costs.

The proposed rule has been reviewed in accordance with the requirements of the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321, et seq.), the regulations of the Council on Environmental Quality (CEQ) (40 CFR part 1500), and OSHA's DOL NEPA Procedures (29 CFR part 11). As a result of this review, OSHA has determined that the proposed standard will have no significant effect on air, water or soil quality, plant or animal life, use of land, or other aspects of the environment.

2. Industry Profile

This section will provide an overview of the industry subsectors covered under the proposed rule. The discussion will include a description of the basic duties performed, the number of employees and establishments, and the financial situations for each SIC group. The proposed standard will cover two four digit SICs: 3731 (Shipbuilding and Repairing) and 4491 (Marine Cargo Handling). SIC 3732 (Boat Building and Repairing) is a separate industry which was covered under the General Industry PEL update.

SIC 3731: Shipbuilding and repairing. The shipbuilding and repairing industry

(SIC 3731) includes establishments which engage in the construction, repair. alteration, conversion, and maintenance of ships, barges and lighters, whether self-propelled or towed by other craft [3]. Ship repair work may range from one-time, emergency corrections of particular problems to overhauls involving scheduled maintenance projects lasting from six months to one year, during which ships are completely refurbished and retrofitted in order to upgrade their equipment to the current state of the art. Shipbreaking, which involves disassembling ships for scrap and components, is also included in SIC 3731, although this activity is seldom performed in the U.S. In addition, many shipyards have been actively soliciting non-marine industrial work involving the same operations typically performed in shipbuilding and repair work, such as steel fabrication, welding, boiler repairs and engine overhauls.

The establishments which comprise the U.S. shipbuilding and repair industry range from very large facilities. employing over 25,000 workers, to firms with as few as 2 workers. Of the shipbuilding and repair facilities in the U.S., the largest 3 percent employ over 70 percent of the total workforce. The Census of Manufactures reported that SIC 3731 contained 605 shipyards operated by 542 companies in 1977. This decreased to 590 shipyards operated by 547 companies in 1987. The Census of Manufactures data are collected every 5 years, and 1987 is the last year data are available from that source. Most major facilities are located in the Gulf/ Mississippi Region, followed by the East Coast, Great Lakes, and West Coast

The U.S. Active Shipbuilding Base (ASB) includes those shipyards which are "open and currently engaged in or seeking contracts for the construction of major oceangoing or Great Lakes ships 1,000 gross tons or over" [11]. During 1989 alone, the U.S. ASB decreased from 19 to 16 shipyards. U.S. ASB shipyards account for about 75 percent of total SIC 3731 employment.

Shipbuilding and repairing is a large scale heavy manufacturing activity which requires both skilled and unskilled labor. Table V–C1 shows the employment trend for SIC 3731 since 1987.

Potential exposures are most likely to result from activities such as welding, painting, abrasive blasting, tank cleaning and grinding. The breakdown of the shipbuilding and repairing industry's workforce by occupational group is shown in Table V-C2.

TABLE V-C1.—TREND IN U.S. SHIPYARD EMPLOYMENT 1980-1989

Year	1980	1981	1982	1983	1984	1985	1986	1987	1988	1989

Source: CONSAD Research Corp., Data to Support a Regulatory Analysis of the Proposed Standard for Shipbuilding and Repairing: Subpart B, Prepared for the U.S. Department of Labor, OSHA under Contract No. J-9-F-4-0024, U.S. Department of Labor, Bureau of Labor Statistics, "Employment and Earnings", 1989.

The primary occupational groups affected by the proposed regulation are welders and painters. Welders fuse metal objects by means of an exyacetylene torch or arc-welding apparatus in the fabrication of metal shapes and in repairing broken or cracked metal objects aboard ships. In addition to performing hand welding or brazing operations, the welder may also lay out guide lines or marks on metal parts and may cut metal with a cutting torch. Depending on the task, welders may be actively engaged in welding for up to eight hours per day. Other groups of employees may work in either the same environment or in adjacent compartments. Among these groups are the outfitting trades, carpenters, electricians, outside machinists and others involved in erecting steel such as riggers and grinders.

Market structure. The domestic market for commercial shipbuilding has decreased dramatically over the past twelve years. Nearly all sales have been lost to foreign producers, especially Japan and South Korea, where most ships can be built for less than the U.S. price. Foreign competitors usually have lower labor costs and often receive generous subsidies from their governments, while labor and material costs are relatively high in the U.S. The U.S. ranked thirty-first in worldwide merchant shipbuilding with only 0.1

percent of the gross tonnage on order

The workload of U.S. shipyards is dominated by U.S. Navy ship construction projects. As of October 1, 1989, 91 military combatant and auxiliary ships were under construction or on order by the Navy, and 2 medium endurance cutters were under construction for the U.S. Coast Guard. Among the 91 Navy ships ordered were 21 T-ships, i.e. auxiliary crane ships, hospital ships, fleet oilers, and ocean surveillance ships. However, Navy ships tend to require large-scale, highly technical production which has benefited the larger shipyards more than smaller shipyards. In 1988, the total value of the work completed by U.S. shipyards was \$8.7 billion in current dollars, down 2 percent from 1987 when adjusted for inflation [9]. Total revenues in 1989 were \$9.1 billion [3].

Despite a declining market for commercial ship construction, shipbuilding and repair facilities in the U.S. continue to invest millions of dollars to improve, expand and modernize their facilities. Over \$195 million was invested in the 1989 fiscal year, and industries planned to invest at least \$250 million in the year ending June 30, 1990 [9]. Such large investments have dramatically increased the capability of U.S. shipyards, although facilities remain substantially underused.

SIC 4491: Marine cargo handling. The Marine Cargo Handling industry includes those facilities which are responsible for the handling of marine cargo from the time of arrival at shipside, dock, pier, terminal, staging area, or in-transit area to the completion of cargo loading or unloading. SIC 4491 also includes establishments which engage in the transfer of cargo between ships and barges, trains, trucks, pipelines and wharves. The maintenance and operation of piers and docks, including related facilities, are also included in this SIC.

Marine terminals are defined as "wharves, bulkheads, quays, piers, docks and other berthing locations and adjacent storage or contiguous areas and structures associated with the primary movements of cargo or

materials from vessel to shore or shore to vessel including structures which are devoted to receiving, handling, holding, consolidation and loading or delivery of waterborne shipments and passengers. including areas devoted to the maintenance of the terminal or equipment. The term does not include production or manufacturing areas having their own docking facilities and located at a marine terminal nor does the term include storage facilities directly associated with those production or manufacturing areas."

For several years, there has been a trend toward public ownership of marine terminals, though most are still privately owned. Because they tend to be operated by or for the exclusive use of a single firm, most privately-owned terminals are directly competitive neither with one another nor with publicly-owned terminals. Privately owned terminals traditionally specialize in bulk cargoes, since large investments are often required in bulk terminal facilities.

Many terminals are publicly owned and leased by private tenants. Stevedoring establishments are firms which contract with a ship's owner, agent, charter operator, or the owner of the cargo to load or unload vessels in ports. The stevedoring firm typically hires longshoremen, usually on a daily basis, from a hiring hall or labor pool of union or nonunion members. The stevedoring labor force size varies directly with the amount of work the stevedoring establishment contracts to perform, which is a function of port activity. At any given time, a stevedoring firm may be working several vessels or none at all. Thus, longshoremen are hired as needed by the stevedoring establishment and discharged upon completion of an individual job. However, some longshoremen, such as equipment room managers or foremen, receive long-term employment commitments from an individual firm and work a standard work week plus required overtime.

There are approximately 57,912 total employees and 1,091 establishments in SIC 4491 [10]. The nature of marine cargo handling work is such that fulltime employees rarely work the typical 2,000 hour work-year. Full-time longshoremen work an average of 1,565 hours per year [5].

Vessels and commodities. Potential exposures to the substances affected by the proposed rulemaking occur during the loading and unloading of a wide variety of commodities. For example, the unloading of vehicles from RO-RO vessels creates a potential for exposure to substances such as carbon monoxide and carbon dioxide. Similarly, the loading of grain into a barge or bulk carrier creates potential exposures to grain dust as well as to any fumigants or pesticides, such as phosphine and methyl bromide, which may have been applied to the grain.

Table V–C3 shows the foreign and domestic waterborne commerce of the United States for 1988 [6]. Vessel types are relevant for addressing potential exposures associated with the shipment of these commodities.

Self-propelled vessels—Bulk Carriers are self-propelled vessels designed to carry bulk commodities such as heavy ores and minerals, pallets and wood chips, coal, and general dry bulk commodities such as grains. Loading a bulk commodity, such as grain, involves a system of conveyors and chutes or spouts. Grain is taken by conveyor from a grain silo to a chute positioned over the open hatch of a ship's hold into which the cargo is loaded. Once the cargo is loaded, one or two longshoremen may be called upon to

level the grain in the hold. These vessels may also be used to carry bulky general freight such as logs or steel.

General tankers are vessels arranged for the carriage of liquic cargoes in tanks integral to the hull. The majority of these vessels carry crude oil, petroleum, and petroleum products. Chemical tankers are vessels structurally arranged for particular services or cargoes, such as asphalt, asphalt bitumen, phosphorus, solvents and various specialty chemicals.

Special tankers are tankers which were designed for a specific type of cargo. The characteristics of these vessels effectively limit their applicability to specialty products. Included in this category are molasses, liquid latex, sulphur, and wine tankers.

LNG/LPG tankers are vessels designed for the carriage of liquified natural gas, liquified petroleum gas, and other manufactured gases and natural gas products.

Break bulk vessels include carriers of refrigerated and unrefrigerated general cargo. Among the break bulk cargoes are fruits and vegetables, lumber, glass, and machinery. Break bulk vessels may be used to transport standardized containers but they are not designed to specialize in containerized cargo.

Roll-On/Roll-Off (RO-RO) vessels are those that are specially designed to carry automobiles, other vehicles, wheeled containers or trailers. RO-RO ships only use the RO-RO method for loading and unloading, in which vehicles are actually driven on or off the ship. Containerized cargo may be transported on the upper deck of a RO-RO vessel.

Containerships are vessels designed exclusively for the carriage of standardized containerized cargo. These vessels are equipped with permanent container cells and have little or no space for other types of cargoes.

Containers are loaded and unloaded usually by cranes and toploaders.

Break bulk, RO-RO vessels and containerships are often grouped together in a broad class as freighters. Both break bulk and RO-RO vessels may be partial containerships, in which one or more, but not all, compartments are fitted with permanent container cells; the remaining compartments are used for other types of cargo. In break bulk and RO-RO vessels, containers are often transported on the upper deck and other cargo is carried in lower decks.

Non-self-propelled vessels—Bulk barges are large double hulled cargo holds without an internal means of propulsion. Virtually all barges used on the inland river system are 195 feet long by 35 feet wide. Most bulk barges have a total draft of 12 feet and are typically loaded so that they draw 9 feet of water. Barges can carry virtually any dry cargo and have an average capacity of 1,500 tons or about 52,500 bushels. Also classified as barges are scows and ocean-going barges. These barges tend to be much larger, have a higher

freeboard and carry most of their cargo on deck.

Tanker barges are double hulled barges designed exclusively to haul liquid cargos. Tanker barges lack an internal means of propulsion but do contain pumping systems and equipment for unloading their cargoes. Tanker barges are not of standardized size but are on the order of 240 feet long by 75 feet wide. Tanker barges do have a standard draft of 12 feet.

Gang size. Table V-C4 summarizes average stevedoring gang size by type of operation. Separate crew sizes are itemized for various ship and barge operations. Crew sizes vary dramatically by type of operation and type of vessel. Crew size may range from 2 for tanker barge loading to 64 for RO-RO operations. Also in Table V-C4 are average cargo handling rates per stevedore work-hour.

Market structure. Table V-C5 shows the annual revenues and profits related to longshoring operations by region. Most economic activity occurs in the Gulf/Mississippi region. This region accounts for about 51 percent of total industry revenues and profits. Annual revenues and profits related to longshoring activities total \$6.6 billion and \$0.3 billion, respectively.

TABLE V-C4.—SUMMARY OF AVERAGE STEVEDORING GANG SIZE AND CARGO HANDLING RATES

Type of operation	Average total on- site steve- dores	Average handling rate per steve- dore work- hour (tons/ hour)
Ship:		170
Break bulk operation	16	5.0

- 3. Employee Exposures and Benefits

Introduction. Employee exposures to the substances included in the scope of this rulemaking are associated with a wide variety of acute and chronic conditions and illnesses. These include sensory irritation, narcosis, organ system dysfunction, chronic respiratory disease, neurological impairment, allergic sensitization, and cancer. Since OSHA's adoption of existing Federal and consensus standard limits in 1971. toxicologic evidence has become available that shows that adverse health effects can occur as a consequence of exposure to many of the substances listed in OSHA's Z tables, and that such health effects occur even when exposures are maintained at the current Z-table limits. In addition, many substances that have come into widespread use or been introduced since 1971 have been shown to be potentially hazardous in the workplace environment. OSHA thus believes that reducing worker exposure to such substances by lowering existing exposure limits or by adding limits for previously unregulated substances will result in a significantly reduced risk of

This section describes both the methodology used to identify maritime workers potentially exposed to the hazardous substances included in this rulemaking and the expected benefits to those workers resulting from lowering permissible exposure levels. An important existing data base for identifying employees potentially exposed to hazardous substances was OSHA's Integrated Management

illness to workers.

Information System (IMIS). The IMIS data were used to project expected benefits resulting from lowering permissible exposure levels of the substances being regulated.

Exposure Profile

Methodology. SIC 3731: Shipbuilding and repairing. For each facility inspected, the IMIS files contained information on the number of employees at the facility, the occupation of each employee sampled at the facility, and the number of employees observed to be potentially exposed to each substance for which personal air samples were collected at the facility.

For each substance sampled within each four-digit SIC, the estimated number of employees potentially exposed to that substance in that SIC was determined by the following formula:

$$\frac{\sum P_t}{\sum F_t} \underset{W=P}{\times}$$

where

P_t=number of employees observed to be potentially exposed to the substance at a facility;

E_t=number of employees at each facility inspected by IMIS;

W=number of workers in the industry in 1989; and

P=estimated number of employees potentially exposed to the substance in the industry.

The estimated number of employees currently exposed above the limits for each substance was calculated using the following formula:

$$\frac{\sum S_t}{\sum T_t} \times P = Z$$

where

S_r=number of samples that exceeded the limit for the substance at all facilities inspected by IMIS in the industry sector;

T_t=total number of personal samples taken for the substance at all facilities inspected by IMIS in the industry sector; P=estimated number of employees

P=estimated number of employees
potentially exposed to the substance in
the industry sector, and

Z=estimated number of workers in the industry sector currently exposed above the limits for the substance.

Some data for shipyards were collected during the survey conducted for the general industry PEL update. The following information was provided:

- The total number of production employees at the facility;
- The number of employees involved in each process used at the facility;

· The substances used or present in

each process;

 The exposure limits used as internal targets or goals at the facility (i.e., OSHA's current limits, ACGIH limits, NIOSH limits, or "Other" limits such as those from material safety data sheets or insurance carriers); and

 Whether employee exposures exceeded the targeted limits for each process/chemical combination present

at the facility.

To estimate the number of employees potentially exposed to a given substance, OSHA assumed that all employees who are involved with processes in which the substance is used or present are potentially exposed. Thus, the formula for estimating the number of employees potentially exposed to a substance in the shipbuilding and repairing industry is:

$$\frac{\sum X_t}{\sum T_t} \times W = P$$

where

X_f=number of employees at the facility who are involved in processes using a given substance;

T_t=total production workforce at the facility:

W=the number of production workers in the industry sector; and

P=estimated number of employees
potentially exposed to the substance in

the industry sector.

To estimate the number of employees currently exposed above the final limits, OSHA relied on survey responses that indicated whether exposure measurements associated with a process exceeded the facility's internal exposure

limits. OSHA interpreted the survey

responses as follows:

(1) OSHA assumed that none of the potentially exposed employees are currently exposed above the limit for any substance associated with a process if:

(a) the revised limit is an ACGIH TLV and respondents indicated that exposure measurements did not exceed ACGIH, NIOSH, or some "other" set of limits; or

(b) the revised limit is a NIOSH REL and respondents indicated that exposure measurements did not exceed NIOSH limits.

(2) OSHA also assumed that all of the potentially exposed employees are currently exposed above the limits for all substances associated with a process if:

(a) the revised limit is an ACGIH TLV and respondents indicated that exposure measurements did exceed OSHA, ACGIH, or some "other" set of limits, or

(b) The revised limit is a NIOSH REL and respondents indicated that exposure measurements did exceed OSHA, ACGIH, NIOSH, or some "other" set of limits.

The number of overexposed workers were then summed for each substance across all facilities that responded to the survey in SIC 3731. In instances where the survey data yielded no information on whether or not employees are exposed above the proposed limit for a substance, and no exposure data were available from IMIS on that substance, OSHA assumed that no workers are overexposed to that substance. It is likely, however, that in some of these cases there are employees exposed above the proposed limits, OSHA believes that it has not necessarily accounted for all employees who are exposed above the proposed PELs for the substances included in this analysis. OSHA, thus, believes that the number of overexposed employees may be understated.

A separate analysis of existing IMIS data was done to determine the effect of proposed limits on MEL (mixture exposure limit) overexposures. To estimate the number of workers over the MEL, employees rather than incidents with either PEL or MEL overexposures were identified. Each sample in the IMIS database listed the occupation of the employee sampled, all substances and levels at which the worker was exposed, and the number of workers similarly exposed. Potential exposures were calculated by adding the total number of full-time equivalent workers in each occupational group potentially exposed to any combination of substances affected by the proposed rulemaking.

The estimated number of employees currently exposed above the MEL for any combination of substances, which includes one or more substances affected by the proposed rule, was calculated using the following formula:

$$\frac{\sum S_r}{\sum T_r} \underset{P=Z}{\times}$$

where

S_t=number of samples that exceeded the MEL at all facilities identified by IMIS for the industry sector. (Note: This number includes any worker exposed above the PEL for any substance, since, by definition, any worker over a PEL would be overexposed to the MEL);

T_f=total number of personal samples involving substances affected by the proposed rulemaking taken at all facilities identified by IMIS for the industry sector; P=estimated number of potentially exposed employees in the industry sector; and

Z=estimated number of workers in the industry sector currently exposed above the limits

ne limits.

SIC 4491: Marine cargo handling. Data from IMIS, a study conducted by Kearney/Centaur, commodity and tonnage data from the U.S. Army Corps of Engineers, and expert judgements were used to estimate worker exposures in SIC 4491. The intermittent work schedules of stevedores caused difficulty in making typical 8-hour TWA measurements. To determine the exposures to hazardous substances in the marine cargo handling industry. OSHA looked at each commodity shipped by water and the number of full-time equivalent workers involved in the processes. Every imported and/or exported, as well as each domestically shipped commodity, was examined for potential exposures.

OSHA looked at the form in which each commodity is shipped, whether in containerized, break bulk, liquid bulk or dry bulk cargo form. OSHA also analyzed commodities requiring the RO-RO method for loading and unloading.

Procedures for loading and unloading the various commodities, potential exposures, and the percentage of stevedores likely to be overexposed were determined.

Once the areas of potential exposure were determined, OSHA estimated the number of full-time equivalent employees involved in the processes and potential exposures.

Estimates of the Number of Potentially Exposed Employees

SIC 3731

The IMIS data base and the survey provided information on the substances posing potential hazards to specific occupational groups in SIC 3731. Table V–C6 shows the occupational groups identified in IMIS, the hazardous substances to which each group is potentially exposed, and the adverse health effects related to exposure.

One of the most widely recognized hazards associated with exposures to airborne substances in the maritime industry involves tank cleaning. Tank cleaners may be potentially exposed to any substance carried in bulk liquid form. Table V-C7 lists liquid substances transported in bulk which are affected by the proposed rulemaking. OSHA estimates that all 843 tank cleaners may be potentially exposed to the substances listed in Table V-C7. Due to the potentially serious nature of the hazards involved and the requirements imposed

by relevant existing standards, employers are generally aware of the need to protect employees during this activity. OSHA believes that the requirements imposed by this proposed rulemaking would not require significant changes in current practices. OSHA requests public comments on this preliminary conclusion.

To obtain an overall estimate of the extent of employee exposures to substances used in SIC 3731, OSHA combined the estimates derived separately from the IMIS and survey data. Where estimates for a given substance could be derived from one data set but not the other, the assessment uses the available estimates

without adjustment. Where estimates could be derived from both data sets for the same substance, the combined assessment is based on the average of the available estimates; this approach has the effect of giving equal weight to estimates derived from either the IMIS or survey data. The results are shown in Table V—C8.

Because an employee may be exposed to more than one substance in a given industry, aggregate estimates of the size of the exposed population are presented as an average of minimum and maximum estimates of potential and overexposures. Maximum estimates of the size of the exposed population assume that no employee is exposed to more than one substance; minimum estimates assume the greatest possible extent of multiple chemical exposure. When minimum and maximum estimates are averaged, the result is OSHA's best estimates of actual exposures. For the shipbuilding and repairing industry, the minimum and maximum estimates of potentially exposed workers are 5,856 and 49,040, respectively. The minimum and maximum estimates of the number of workers overexposed are 1,245 and 4,315. OSHA's best estimates of the actual number of potentially exposed and overexposed workers are 27,448 and 2,780, respectively.

The majority of overexposures are to welding fumes and methyl isoamyl ketone. The activities for which these exposures occur are welding and painting. OSHA believes that overexposures may occur during grinding operations. IMIS data, however, do not provide documentation to support this. OSHA requests information on this subject.

Bulk Liquid Cargoes*	843	0			843	

*The 843 workers in this category represent tank cleaners which may be potentially exposed to bulk liquid cargoes listed in Table V-C7. Source: U.S. Department of Labor, Occupational Safety and Health Administration, Office of Regulatory Analysis.

When the MEL methodology was used (instead of single or specific substance exposure incident data described above) 22,267 workers were estimated to be potentially exposed to one or more substances affected by the proposed rule, and 2,717 workers had exposures which exceeded proposed PELs or MELs. About 734 of these overexposures exceeded the MEL without exceeding individual PELs. The MEL approach resulted in slightly less control technology and cost than controls needed for specific substance incidents. The reason for electing the more conservative substance specific cost methodology was influenced by the need to develop substance specific benefits.

Since overexposure results from the application of a mathematical formula, the attribution of health effects (and consequently benefits) becomes a problem. There is very little health science data on the combination effects of chemicals acting synergistically (formaldehyde and wood dust, asbestos and tobacco smoke are notable exceptions). Traditionally the health effects related to individual substances have provided the basis with which to develop potential benefits of proposed OSHA rules. The potential benefits of avoiding MEL overexposure are very difficult to quantify since individual substances within a mixture often

produce different health effects. There is a practical problem of correctly apportioning risk reduction factors across all chemicals in a mixture. While mathematically possible, it is unclear that health science can provide guidance as to what risk reduction factors can be assigned to the individual components in a mixture. Absent this guidance, OSHA focused on risks posed by individual substances and has made benefit projections on this basis. This focus on individual substances influenced the cost methodology and insured consistency on the separate sides of the cost to benefit equation (i.e., costs related to individual substance control and benefits unique to individual substance exposures).

On balance, this approach probably has the effect of slightly exaggerating estimated costs of the proposed PELs. Benefits may also be exaggerated to the extent that multiple overexposures are concentrated on a few workers (the methodology adopted assumes they are not). As health science advances, and the true risk of mixture exposures becomes better defined, future analysis may find higher risk and, as a result, potential benefits in reducing MEL overexposures.

SIC 4491

Exposure potentials exist from the loading and unloading of a wide variety of commodities.

Risks of exposure during the loading and unloading of containerized cargoes exist only if there is a breakage. Leaks in containerized cargoes are rare. If a leak does occur, all longshoremen are removed from the site and specialists are called in to clean up the spills.

There is also little risk of worker exposure to hazardous substances during the loading and unloading of bulk liquid cargoes. The loading or unloading of liquid cargoes involves connecting pipes from the valve of the tank holding the cargo to the valve of the tank to which the cargo is to be loaded. The valves are opened and the cargo is pumped only after hook-up is complete. The operation of the pumps is done from a console located away from the deck. Stevedores are involved only in the hook-up and disconnection of the pipelines and are not required to be present during the actual transfer of cargo. Any potential exposures would be negligible and of short durations.

The loading and unloading of dry bulk cargoes creates a potential for exposure to various dusts, fumigants and pesticides. The loading and unloading of grain, for example, creates a potential for exposure to grain dust, as well as to any pesticide or fumigant applied to the grain. Generally, grain handling poses little hazard to stevedores. Grain is usually loaded using a system of conveyors and chutes or spouts. Grain is

moved by electric conveyor from dock to ship and dropped through the spout into the hold of the ship [2]. This procedure may take several days, depending on the size of the cargo. Besides someone to observe the grain loading, no other workers are involved during this procedure. Workers may be called upon to level the grain in the hold of a vessel only after the grain is loaded. Any exposures to grain dust would be of short duration. A potential does exist for overexposures to occur during the breakdown of conveyors or other equipment necessary in this loading procedure. However, OSHA has no evidence of any overexposures and requests additional information.

There has been concern about worker exposures to fumigants, such as ethylene dibromide (EDB), which are known carcinogens or known to cause serious illnesses such as permanent liver and kidney diseases [3]. However, risks of exposures have declined dramatically since the move away from liquid applications of pesticides and fumigants and the banning of EDB use in the United States. Phosphine and methyl bromide are the fumigants commonly used in grain handling which are affected by the proposed rulemaking. These substances are in the form of pellets which are dropped through tubes into the grain in the hold of a vessel. The pellets dissipate while the cargo is in transit. This procedure for pesticide/ fumigant application greatly reduces the risk of exposure to fumigants and pesticides.

Roughly 79 million tons of grain are handled by stevedores each year. The average handling rate per stevedore work hour for conveyor loading is 96.2 tons. Applying this rate to the total tonnage handled and assuming a 2,000 hour work-year yields 411 full-time equivalent workers potentially exposed

to grain dust, phosphine and methyl bromide each year. No stevedores are likely to be overexposed to these substances.

Significant exposures exist during RO-RO and forklift operations. Of the substances affected by the proposed rulemaking, the most significant exposures in the marine cargo handling industry are to carbon monoxide and portland cement.

The RO-RO method of loading and unloading creates a risk of exposure to substances such as carbon monoxide and carbon dioxide. Carbon monoxide exposures are the most significant. According to Kearney/Centaur approximately 1,847 full-time equivalent employees are involved in RO-RO operations. Most RO-RO ships have good ventilation systems which reduce carbon monoxide levels.

The loading and unloading of break bulk cargoes involving the use of forklifts also create a potential for exposure to carbon monoxide. Although most break bulk ships are well ventilated, some older break bulk ships lack sufficient ventilation. There has, however, been a move towards the use of electric and diesel powered forklifts. There are roughly 2,000 full-time equivalent workers involved in forklift operations.

OSHA estimates that, under existing conditions, approximately 20 percent of RO-RO and forklift operators would not be in compliance with the proposed PEL for carbon monoxide. IMIS data support this estimate. Applying this percentage to the 3,847 full-time equivalent workers potentially exposed to carbon monoxide yields 769 overexposed workers.

Overexposures to portland cement are likely to occur during the unloading of dry bulk cement. Approximately 24.1 million tons of building cement are unloaded each year. Of this amount,

roughly 90 percent (21.7 million tons) is shipped in dry bulk cargo form. Dry bulk cement is unloaded either by pneumatic means (vacuums) or by clamshell buckets. Roughly 98 percent of the tonnage (21.3 million tons) is vacuumed and 2 percent (0.4 million tons) is unloaded by clamshell.

The average handling rate per stevedore work-hour is 96.2 tons per hour for dry bulk operations and 45.9 for clamshell operations. Applying these rates to their respective tonnages and assuming a 2,000 hour work-year yields 115 full-time equivalent workers potentially exposed to portland cement each year. OSHA believes that roughly 50 percent of these workers would be under the proposed PEL for portland cement, leaving 58 full-time equivalent workers overexposed.

Potential exposures also exist during the loading of dry bulk cement. Approximately 10.5 million tons of building cement are loaded each year. Of this amount, roughly 9.5 million tons are in dry bulk cargo form. Applying the 96.2 tons/hour handling rate yields about 49 full-time equivalent workers potentially exposed to portland cement annually. None of these workers are likely to be overexposed.

Once the cargo is loaded or unloaded, the hold is usually either cleaned in preparation for new cargo, or trimmed to level the cargo in the hold.

Approximately 31.2 million tons of bulk cement were loaded or unloaded in 1989. The average barge or bulk cargo ship has four holds and carries 30,000 tons. Assuming that it takes three workers and 2.5 hours/worker to clean or trim a hold, 16 full-time equivalent workers are potentially exposed to portland cement. Roughly 8 of these workers are estimated to be overexposed.

TABLE V-C9.-POTENTIAL AND OVER EXPOSURES SIC 4491

Substance			Potential exposures	Over exposures
	Process	Primary basis for limit	(FTE workers)	
Carbon Monoxide	RO—RO Operations	Biochemical/Metabolic Effects	3,847	769
Coal Dust	Sweeping/Trimming	Respiratory Effects	2,673	0
Cobalt, Metal, Fume and Dust	Longshoring	Sensitization	2,/35	0
Hydrogen Fluoride	Grain Handling Longshoring	Respiratory Effects	The second secon	0
Methyl Bromide	Grain Handling	Neuropathy	411	0
Phosphine	Grain Handling	Systemic Toxicity	411	66
Portland Cement	Dry Bulk Cement Handling	Physical Irritation	180	0
Total			13,082	835

Based on IMIS data, consultation with industry experts and data compiled by consultants under contract with OSHA, other exposures are likely to exist in addition to those mentioned above. These include exposures during various other bulk cargo handling activities; these estimates are shown in Table V–C9, along with the exposures discussed earlier.

Summary

As shown in Table V-C10, there are an estimated 40,530 workers potentially exposed and 3,615 workers overexposed to substances affected by the proposed rulemaking.

TABLE V-C10.—SUMMARY OF POTENTIAL AND OVER EXPOSURES MARITIME IN-DUSTRY

BENEFITS

Illnesses

Illness rates are derived from the 1989 BLS Occupational Injuries and Illnesses data base. These rates are expressed as the annual number of illnesses per 100 full-time equivalent employees.

Reducing employee exposures to hazardous substances to levels below those associated with adverse health effects will result in a decrease in the number of illnesses.

OSHA estimated the number of annual illnesses that would be averted by applying current rates to the estimated number of overexposed workers in each SIC.

Based on the Bureau of Labor Statistics 1989 publication of Occupational Injuries and Illnesses in the United States, the occupational illness rate for the shipbuilding and repairing industry is 5.8 per 100 full-time workers (total cases) and 1.8 per 100 full-time workers (lost workday cases). Approximately 30 percent of the illnesses represented by these illness rates (1.74 total and 0.54 lost workday) are addressed by the proposed rule. while 70 percent of the illnesses are the result of physical agents, repetitive motion, etc. The illness rates published by BLS only include cases documented and recorded by employers. In addition, a large number of chronic illnesses resulting from exposures in the workplace may never be reported, since long latency periods make it difficult for employers and physicians to diagnose illnesses as being work related. Illness rates, therefore, tend to understate the actual number of occupationally related

illnesses. OSHA's best estimate is that these illness rates may understate the actual number of occupationally related illnesses by a factor of 5.

Applying these illness rates to the average number of overexposed workers in SIC 3731 yields 242 total illnesses, of which 75 are lost workday cases.

OSHA's best estimate is that 80 percent (194 total and 60 lost workday) of these illnesses would be avoided annually as a result of the proposed rule.

The occupational illness rate for the marine cargo handling industry is reported to be 0.2 per 100 full-time workers (total cases) and 0.1 per 100 full-time workers (lost workday cases). Approximately 40 percent of the illnesses accounted for are addressed by the proposed standard. A factor of 5 was applied to these illness rates to account for the understatement.

Applying the illness incidence rates to the number of overexposed workers in SIC 4491 yields 3 total illnesses, 2 of which are lost workday cases. Assuming an 80 percent effectiveness rate, the proposed rule should prevent 2 lost workday illnesses.

The estimated number of annual illnesses prevented by the proposed rule for both industry subsectors are presented in Table V-C11. In addition to OSHA's best estimate of an 80 percent effectiveness level, a sensitivity analysis using 70 percent and 90 percent effectiveness rates is also presented.

Fatalities

TABLE V-C11.—REDUCTION IN ILLNESSES

	Number of illnes	Illnesses prevented by effectiveness							
Industry subsector SIC code	Total LWD	nom exposures		70%		80%		90%	
		TL	LWD	TL	LWD	TL	LWD		
Shipbuilding and Repairing SIC 3731 Marine Cargo Handling SIC 4491	242	75 2	169	53	194	60 2	218	68	
Total	245	77	171	54	196	62	221	69	

Sources: Ú.S. Department of Labor, Bureau of Labor Statistics, 1989 Occupational Injuries and Illnesses in the United States. U.S. Department of Labor, Occupational Safety and Health Administration, Office of Regulatory Analysis.

There are no statistical data on fatalities from work related illnesses in the maritime industry. However, there are studies which show that fatalities do result from exposures to substances included in OSHA's Z-Table. For example, a study of silicosis in sandblasters conducted in the early seventies showed that deaths did result from silica exposures in New Orleans shipyards [9]. Although the actual level for silica remains unchanged, OSHA believes the new formula, which is easier to understand and allows for

more accurate monitoring, will increase compliance.

There are an estimated 1,245 workers overexposed to welding fumes, for which there is currently no PEL. Welding fumes often cause metal fume fever and sometimes damage the small airways, causing interstitial pneumonia at levels above the proposed PEL.

Carbon monoxide, is known to cause fatalities at exposures above the proposed PEL.

Because some substances are known to cause fatalities at high exposure levels, OSHA believes that the proposed rule will prevent fatalities. OSHA estimates that annual fatalities avoided could average 1–2 annually.

Summary

OSHA estimates that 196 total illnesses and 62 lost workday illnesses would be avoided annually as a result of the proposed rule. OSHA also believes that fatalities will be prevented as a result of the proposed rule, probably 1–2 on average, annually.

4. Assessment of Nonregulatory Alternatives

For a full discussion on the need for and the appropriateness of a regulatory solution to address occupational exposures to air contaminants, see section V.B.4. of this preamble.

5. TECHNOLOGICAL FEASIBILITY

Introduction. This section presents a technological feasibility analysis of the maritime industry's ability to meet OSHA's proposed permissible exposure

limits (PELs).

The control of workplace exposures to toxic chemicals involves combining a variety of standard techniques to solve problems unique to each situation. OSHA believes that proposed levels can be met using currently available controls and equipment and work practices. Consistent with OSHA regulations and policy, this section examines the feasibility of engineering controls and work practices to control employee exposures, in preference to personal protective equipment. However, under certain circumstances. respiratory protection may be necessary.

Engineering controls. Engineering controls involve the use of local exhaust

ventilation, general ventilation, isolation of the worker and enclosure of the source of emissions process modifications, equipment modifications, and substitution of non-hazardous chemicals. These methods may be used alone or in combination of any two or more controls depending upon the needs of the specific situation.

Perhaps the most widely used technique for controlling chemical exposures is the use of ventilation. General ventilation uses the movement of air within the general work space to displace or dilute the contaminant with fresh outside air. General ventilation is not typically the preferred control method in most operations due to the large volumes of air movement required. Local exhaust ventilation is concentrated on moving smaller volumes of air, exhausted from the point at which contaminants are generated thereby removing contaminants at the source.

Personal protective equipment. Where it is impractical to apply engineering or work practice controls, or where their application will not consistently reduce employee exposures below the proposed PELs, personal protective equipment such as respirators or dust masks may be used to prevent or reduce exposures.

SIC 3731: Shipbuilding and repairing.
The major air contaminants in the shipbuilding and repairing industry result from welding and painting.
Welding. OSHA has determined that

Welding. OSHA has determined that welding activities cause overexposures to the following substances (shown with proposed PELs):

Cobalt, Metal, Fume & Dust (0.05 mg/m³)

Nickel (Soluble Compounds) (0.1 mg/m⁸)

Styrene (50 ppm or 215 mg/m³)
 Welding Fumes (5 mg/m³)

• Zinc Oxide Fume (10 mg/m³ STEL)

OSHA believes that all of the proposed PELs for these substances can be achieved using portable, local exhaust systems comprised of a vaneaxial suction fan, flexible duct, and portable capture hood.

Painting. OSHA determined that overexposures during painting activities exist for the substances shown below

(with their proposed PELs):

• N-Butyl Alcohol (50 ppm (C) or 150 mg/m³(C) SKIN)

 Cyclohexanone (25 ppm or 100 mg/ m³ SKIN)

 Methyl Isoamyl Ketone (50 ppm or 240 mg/m³)

Stoddard Solvent (100 ppm or 525 mg/m³)

OSHA believes that the proposed PELs for painters can be met by using a portable exhaust system consisting of a vane-axial suction fan, flexible duct, and portable capture hood. In cases where ventilation cannot maintain the chemical concentration below the PEL, painters would require respirators. Gloves should be worn to reduce dermal exposure to substances for which OSHA has a skin notation.

Other exposures. OSHA also estimated that a very small number of plastics fabricators are overexposed to trimellitic anhydride which has a PEL of 0.005 ppm or 0.04 mg/m³. This PEL could be achieved using engineering controls similar to those identified for welding

and painting.

SIC 4491: Marine cargo handling—RO-RO operations and break bulk forklift operations. Carbon monoxide overexposures result from RO-RO and break bulk forklift operations. The new PEL for carbon monoxide is 35 ppm or 40 mg/m³ TWA and a ceiling level of 200 ppm or 229 mg/m³. This PEL can be achieved using a vane-axial fan and flexible duct.

Clamshell operations. Clamshell operations have been determined to cause overexposures to portland cement. Sealed lips and dust covers are available to seal the openings in the clamshell buckets through which particles are likely to escape and reach the clamshell operator. These controls should be sufficient to reduce exposures below the proposed 10 mg/m³ total dust and 5 mg/m³ respirable fraction levels.

Trimming/hold cleaning. All overexposures which result from trimming (leveling dry bulk cargoes in hold) and cleaning holds can be brought below the proposed PELs using personal protective equipment. The use of engineering controls in these cases is believed to be impractical.

Summary. Since all proposed PELs can be achieved using currently available engineering controls and personal protective equipment, OSHA has determined that the proposed standard is technologically feasible.

6. Costs of Compliance

Introduction. Costs are related to engineering controls and personal protective equipment needed for specific processes which involve the use of hazardous substances. These costs are presented in this section. Costs of compliance result from the purchase, installation, operation and maintenance of equipment to maintain workers' exposures at or below the levels specified in the proposed standard.

Costs of Compliance. The following operations have the potential for worker overexposure and will incur costs:

SIC 3731

- · Welding
- · Painting/coating

SIC 4491

- Loading and Unloading of Bulk Cement
- -Clamshell Operations -Trimming/Cleaning
- Non-Electric Forklift Operations within vessels
 - · RO-RO operations

This section summarizes for each process: (1) The extent of current worker exposure, (2) the additional controls that will be needed to reduce worker overexposures, and (3) the costs that facilities in the maritime industry will incur to come into compliance with the proposed PELs.

SIC 3731-Welding. Welding is an integral part of the shipbuilding and repairing Industry. Fumes and gases from welding and cutting cannot be easily classified. In welding procedures, the composition of the fumes is determined by the electrode or consumables themselves, coatings on the work (e.g., paint, galvanizing, or plating), contaminants in the atmosphere (e.g., halogenated hydrocarbon vapors from cleaning and degreasing activities), etc. Thus, fumes include those originating from volatilization, reaction, or oxidation of consumables, base metals and coatings, and the atmospheric contaminants. In Section 3, it was determined that welders are currently overexposed to cobalt, nickel, styrene, welding fumes and zinc oxide fume.

It is assumed that exposures are a result of welding in semi-enclosed environments (i.e. the hull of a ship). An estimated 1,612 workers or 58 percent of all overexposed workers in SIC 3731 are welders. To control these exposures, OSHA believes it will be necessary to install portable, local exhaust systems comprised of a vane-axial suction fan, flexible duct, and portable capture hood. Costs for these systems are broken down as follows: \$1,850 for a vane-axial suction fan which pulls 2000 cfm and uses a 0.5 hp electric motor (including purchase, installation/hookup); \$262 for the 100 feet of duct made of a flexible fiberglass coated fabric with a corresion resistent metal helix and a 5" diameter (including purchase, installation/ hookup) @ \$2.62 per foot; and \$150 for a portable hood with a 5"×10" outlet and a 5" diameter inlet (including purchase, installation/hookup). This results in a total investment cost of \$2,262. Assuming a useful life of 5 years, and a 10 percent discount rate, the annualized cost for a portable local exhaust system is \$597.

Annual costs consist of labor to move the system and manipulate the hood during welding, electricity to power the fan, and annual maintenance costs. Labor required to move a portable system into position and manipulate the hood during welding is estimated to be \$780 per year, per system. This is derived by assuming that it takes 10 minutes to set up the system. If the system is set up daily throughout the year, this is equivalent to 43.33 hours a year [(10 mins./day)/(60 mins./ hour] \times (5 days/week) \times (52 weeks/ year). Assuming the labor rate for a nonsupervisory worker in SIC 3731 with 30% benefits is \$18 per/hour, the labor cost to set up the system is estimated to be \$780 per year [43.33 hrs./year x \$18 per/hr.). Maintenance costs are estimated to be 10% of the capital cost. In the case of this system, it is equivalent to \$226 per year (0.1 x \$2,262).

The cost of electricity for operating the system is estimated to be approximately \$39 per year. Since one horse power (hp) is equivalent to 0.746 kilowatts, the 0.5 hp generated by fan uses 0.373 kilowatts per hour. Applying the average national electricity rate of \$0.05/kwh, for five days a week for the entire year, the cost is equivalent to \$39 per year (0.373 kw/hr.×8 hrs./day×5 days/wk.×52 wks/yr.×\$.05/kwh). The total annual operating and maintenance cost for the portable local exhaust system is calculated to be \$1,045 per year (\$780+\$39+\$226).

The total annualized investment cost plus the annual operating and maintenance cost is \$1,642 per year (\$597 + \$1,045). It was assumed that one portable local exhaust system will be needed for each of the 1,612 overexposed welders. The total annualized cost of preventing welding overexposures to substances for which new or updated PELs are proposed is estimated to be \$2,646,904 (1,612 workers overexposed × \$1,642 per year).

Painting and plasticizing. Painting is also an integral part of the shipbuilding and repairing industry. Chemicals present in paints or coatings are a potential source of overexposure. In Section 3, it was determined that painters are currently overexposed to several different chemicals for which new or updated PELs are being proposed. These chemicals are n-butyl alcohol, cobalt, cyclohexanone, methyl isoamyl ketone, nickel, and stoddard solvent.

(There is minimal exposure in plastics fabrication. A small number of plastics fabricators (10) in the shipbuilding industry were estimated to be over exposed to trimellitic anhydride, a colorless solid used in preparation of resins, adhesives, and polymers. The data obtained for plastics fabricators and painters are combined in this analysis since the controls required per exposed worker are roughly the same.)

Overexposures result from inadequate engineering controls or the non-use of full protection respirators. Of the workers in SIC 3731 who are overexposed to a combination of chemicals affected by the proposed rulemaking, roughly 42 percent (1,168 workers) are painters. OSHA believes that exposures can be reduced to the proposed levels using portable, local exhaust systems comprised of a vaneaxial suction fan, flexible duct, and a portable capture hood. In cases where ventilation cannot maintain the chemical concentration below the proposed PEL, the painter (or plasticizer) must be provided with the proper respiratory equipment. Gloves will be necessary to reduce dermal exposure where skin notations are present. Costs for putting together a system to control exposure are broken down as follows: \$1,975 for a 4,000 cfm vane-axial fan which uses a 1 hp electric motor (including purchase, installation/ hookup), \$262 for 100 feet of duct made of a flexible fiberglass coated fabric with a corrosion resistent metal helix and a 5" diameter (including purchase, installation/hookup) @ \$2.82 per foot, and \$150 for a portable hood with a 5"x10" outlet and a 5" diameter inlet (including purchase, installation/ hookup). Engineering controls may not be capable of maintaining chemical concentrations below the proposed PELs in all operations. For some maintenance and repair work and work in confined spaces, full-face powered air purifying respirators will be needed to supplement engineering controls. OSHA estimates that of the 1,168 overexposed workers in this activity, roughly 30 percent will need such respiratory protection. Respirator costs are estimated to be \$495 each. Engineering controls and PPE result in a total investment cost of \$2,882 (\$1,975+\$262+\$150+\$495). Assuming a useful life of 5 years, and a 10 percent interest rate, the annualized cost for the system is \$760.

Annual costs include labor time to move the system and manipulate the hood during painting, electricity to power the fan, and annual maintenance costs. Labor required to move the portable system for work and to manipulate the hood during painting is estimated to be \$1,170 per year, per system. This is derived by assuming that 15 minutes is required to set up the system. If set up daily throughout the

year, total time is equivalent to 65 hours a year [(15 mins./day)/(60 mins./hour)] × (5 days/week) × (52 weeks/year). Assuming the labor rate for a nonsupervisory worker in SIC 3731 with 30% benefits is \$18 per hour, the labor cost to set up the system is estimated to be \$1,170 per year (65 hrs./year × \$18 per/hr.). Maintenance costs are estimated to be 10% of the capital cost. In the case of this system, it is equivalent to \$288 per year (0.1 × \$2,882).

The cost of electricity for operating the system is estimated to be approximately \$78 per year. The 1 hp fan uses 0.746 killowatts per hour.

Applying the \$0.05 electricity rate and assuming that the system is operated eight hours each day for five days a week for the entire year, the cost is equivalent to \$78 per year (0.746 kw/hr.×8 hrs./day×5 days/wk.×52 wks/yr.×\$.05/kwh).

The total annual operating and maintenance cost for the portable local exhaust system is calculated to be \$1,536 per year (\$1,170+\$78+\$288). The total annualized investment cost plus the annual operating and maintenance cost is \$2,296 per year (\$760+\$1,536). It is assumed that each overexposed worker will also require one full-face powered air purifying respirator. Overexposures to n-butyl alcohol and cyclohexanone will require the use of gloves to prevent dermal exposures. The unit cost for a pair of gloves is \$4.33; each pair is assumed to last 5 days. Applying these rates to the 404 overexposed workers results in an annual cost of \$87,466. Thus, the total annual cost of preventing painting overexposures to substances affected by the proposed rulemaking is estimated to be \$2,769,194 [(1,168 workers overexposed × \$2,296 per year)+\$87,466].

Summary. Table V-C12 shows the compliance costs for SIC 3731. Total annualized costs are \$2,646,904 for welding operations and \$2,769,194 for painting. Overall cost of compliance for SIC 3731 is \$5,416,098.

SIC 4491.—RO-RO and Break Bulk Forklift Operations. Carbon monoxide exposures occur during RO-RO and forklift operations which are conducted within the confines of ships lacking adequate ventilation. An estimated 769 workers are overexposed to carbon monoxide.

The control system for carbon monoxide exposures consists of a vane-axial fan, tripod, transport cart, duct storage cannister and wired supported flexible duct. The average cost of this control system is a \$2,590 per unit investment cost. Amortizing this cost at 10 percent over 5 years results in an annualized investment cost of \$683.

TABLE V-C12.—COMPLIANCE COSTS FOR SIC 3731 BY OPERATION

		Painting			
Cost	Welding		Skin protection	Total

Number of units required. Total cost	1,612 \$2,646,904	1,168 \$2,681,728	20,200 \$87,466	\$5,416,0	

Source: U.S. Department of Labor, Occupational Safety and Health Administration, Office of Regulatory Analysis.

The labor required to move each unit is \$1,625 per year. The cost was determined assuming an average wage rate of \$25, including benefits and assuming that 15 minutes is required to set up the unit [(15 mins./day)/(60 mins./hr.)×(5 days/wk.)×(52 wks./yr.)×\$25/hr].

The electricity required to run each unit is \$78. This cost was determined by applying the \$0.05 per kwh rate to the electricity required to power the 1 hp motor of the unit [(1 hp)×(0.746 kw/hp)×(8 hrs./day)×(5 days/wk.)×(52 wks./yr.)×(0.05/kwh)]. The operating costs, estimated to be 10 percent of the investment costs, equal \$259 per unit.

The annual recurring costs of compliance per unit total \$1,962 (\$1,625 + \$78 + \$259).

The annualized cost, per unit, to reduce exposures to carbon monoxide is \$2,845 (\$683 + \$1,962).

The average gang size for RO-RO operations and break bulk forklift operations is 12 workers, which yields approximately 64 gangs. Assuming that one control is required per gang, the

total annualized cost for reducing exposures to carbon monoxide is \$169,280.

Portland cement exposures. Exposures to portland cement in marine cargo handling (SIC 4491) occur during the loading and unloading of dry bulk cement. Overexposures occur during clamshell operations. An estimated 66 workers are overexposed to portland cement (58 during clamshell operations and 8 during trimming and cleaning).

Sealed lips and dust covers can be used to reduce portland cement exposures for clamshell operators. The average cost of a sealed lip and dust cover is \$3,650. Amortizing this investment cost at 10 percent over 5 years yields a \$963 annualized cost.

Annual maintenance and operation costs for each unit are estimated to be 10 percent of the investment cost or \$365.

The annualized cost for clamshell operations, therefore, is \$1,328 per unit. Assuming that 58 units will be required, the total annualized cost to reduce

portland cement exposures during clamshell operations is \$77,024.

Overexposures to portland cement during trimming and cleaning operations will require the use of disposable dust masks to reduce exposures. Approximately 34.6 million tons of portland cement are loaded and unloaded per year. Of this amount, about 90 percent or 31.2 million tons are transported in dry bulk cargo form. Assuming that the average barge has 4 holds and carries 30,000 tons, holds are trimmed or cleaned approximately 4,160 times per year. The average cost of a dust mask is \$1.59 and an average of 3 workers are required to trim or clean each hold. This indicates that 12,480 disposable dust masks and \$19,843 will be required annually to reduce exposures to portland cement.

Summary. Table V-C13 shows compliance costs for SIC 4491. Total costs are \$169,280 for RO-RO and forklift operations, \$77,024 for clamshell operations and \$19,843 for trimming and cleaning operations. Total annualized cost for SIC 4491 is \$266,147.

7. Economic Impacts

Introduction. This section will assess the economic impact of the proposed standard on firms involved in maritime operations.

Economic impact—Compliance costs. As shown in Table V-C15, compliance costs total \$5,682,245, with 96% borne by shipbuilding and repairing facilities and 4% borne by longshoring facilities. The greatest portion of this dollar amount will be incurred by shipbuilding and repairing facilities to reduce welding and painting exposures to levels below the proposed PELs.

The costs per affected employee at risk for SIC 3731 and SIC 4491 are shown in Table V-C16.

Costs as a percent of revenue and profit. Revenue and profit estimates, as well as estimates of costs as percentages of revenues and profits, for the maritime industries are shown in Table V-C17. Estimates of costs as percentages of revenues are less than 0.07 percent for both industry subsectors. Compliance costs as percentages of profits for both SIC

groups range from 0.09 percent and 1.13 percent, with an average of 0.75 percent.

TABLE V-C15-COMPLIANCE COSTS FOR MARITIME INDUSTRY

Industry sector	Compliance
SIC 3731:	
Welding	\$2,646,904

irce: 1989 Dun & Bradstreet Financial Data

U.S. Department of Labor, Occupational Safety and Health Administration, Office of Regulatory Analysis.

These costs are clearly feasible. Most shipbuilding costs are born by the U.S. government for the purchase of warships. Federal contracts require compliance with OSHA regulations, so shipbuilding costs will be passed forward. In any event, costs are tiny in relation to sales and small in relation to profits. The ship repair costs for the civilian sector will be tiny and clearly feasible if absorbed, but are likely to be passed forward because repairs are done in the U.S. when the place of the breakdown or scheduling makes it necessary to be done here. The costs for longshoring, being so tiny as to be inconsequential, are clearly feasible.

Regulatory flexibility. Pursuant to the Regulatory Flexibility Act (Pub. L. 96–353, 94 Stat. 1164 [5 U.S.C. 60 et seq.]), the Assistant Secretary has made an assessment of the standard and has concluded that it will not have a significant impact upon a substantial number of small entities. If a small firm is defined as one that employs fewer than 20 workers, then nearly 50 percent of the firms in maritime would be

classified as "small".

The important criterion of a regulatory flexibility analysis is whether the standard will impose significant costs upon small entities, whether it will have relatively greater negative impact on small entities than on large ones, and whether it will benefit large firms, thereby putting small firms at a competitive disadvantage.

If the costs of compliance for small firms are relatively minor and proportional to the size of the firm, then there is no significant differential effect. The standard does not require any significant capital expenditures, and the compliance costs will tend to be proportional to the level of employment. The analysis showed that declines in profitability expected to result from the rule are not expected to be significant.

Any differential impact on small firms is expected to be insignificant in view of the very small magnitude of compliance costs relative to the overall operating costs for all firms. The significance of the differential impact on profits is further reduced by the likelihood that all firms in the industry should be able to pass a substantial portion of their compliance costs on to consumers. For these reasons, OSHA concludes that small entities will not be significantly affected by the standard.

Other Effects

International trade. The standard is not likely to have any effect on

international trade because of the extremely small magnitude of any price increase that will be required for passing forward compliance costs.

Environmental. The rule and its major alternatives have been reviewed in accordance with the requirements of the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321, et seq.), the regulations of the Council on Environmental Quality (CEQ) (40 CFR part 1500), and OSHA's DOL NEPA Procedures (29 CFR part 11).

The OSHA standard contains provisions for reducing exposures to hazardous substances, and is not expected to have any significant

environmental effects.

D. Preliminary Regulatory Analysis for Agriculture

1. Industry Profile

Introduction. This chapter examines sectors affected by the proposed permissible exposure limit (PEL) update for Agriculture. Based upon a review of several sources, it has been determined that over 782,000 workers, employed at approximately 74,000 establishments, within SICs 01-09, are at risk of potential exposure to substances found on OSHA's Z tables. This chapter summarizes the affected sectors and presents an industry profile detailing the number of establishments, employment and financial characteristics of establishments potentially affected by OSHA's proposed rule. Specifically considered in this industry profile are establishments categorized within SIC 01, agricultural crop production; 02, agricultural livestock production; and 07, agricultural services. Forestry, 08 and fishing, hunting and trapping, 09 are also covered in this report.

Introducing permissible exposure limits in agriculture will not only bring the United States into line with such countries as the United Kingdom and the Federal Republic of Germany regarding the protection of agricultural workers from airborne contaminants, but it will provide consistency in coverage and

protection to all U.S. workers from airborne contaminants.

Profile. Industries involved SICs 01 through 09 in the United States are composed of a large group of diverse establishments, all of which are engaged in various aspects of production and service. The establishments range in physical size from a few acres to thousands of acres, and their purpose and organization can be vastly different (ranging from a small dairy farm in Maine to a huge wheat farm in Kansas).

Concerning the agricultural sector, a continuing trend has been a reduction in the number of employees necessary for operations through increased reliance on automation. Although this trend has leveled off in the past few years, the net result has been that a few large producers with many employees account for a very large share of total production.

Summary of affected establishments and population at risk. Estimates of the number of establishments potentially affected by the proposed standard were developed by Meridian Research Inc.[1], based on the Census of Agriculture[2], Farm Labor[3], and the Agricultural Work Force of 1987[4]. Due to the seasonality of agricultural production and the inability to obtain data which precisely identified the number of agricultural establishments employing more than 10 workers at any one time during the year, SIC groups affected by the proposal were separated into two sections, (1) agricultural production and (2) agricultural services, forestry, fishing,

Agricultural Production

hunting and trapping.

Cash Grains. For the grain sector (SIC 011), the number of workers on large farms was derived by relying on information describing labor requirements for grain production and a size breakout of the industry by acreage. Between 1981 and 1985, 3 hours of labor were required to produce and harvest 1 acre of grain[5]. Knowing that employees at grain facilities work an average of 10 hours per day and 90 days per year[2], it is estimated that a workforce of 11 employees can be expected to produce and harvest 3,300 acres of grain. Applying this figure to statistics from the 1987 Census of Agriculture[2] it is estimated that there were 576 grain farms with over 3,000 acres or more in 1987, representing .1 percent of all grain farm establishments. Because estimates of employment on large farms are not available from any

published sources, it is assumed that each of the large grain farms employed slightly more than 11 employees in 1987, this equates to approximately 6,350 workers.

Crops Other Than Grain. To calculate the estimated number of potentially exposed workers and establishments in crops other than grain (SICs 013 through 018), estimates developed in support of OSHA's Field Sanitation standard were used[6]. Table V–D1 shows the estimated number of workers and establishments presented for SIC codes 013 through 018 in the Regulatory Impact Analysis for the Field Sanitation standard. It is estimated that 492,000 employees work on the estimated 58,000 farms that employ 11 or more workers in these sectors.

For the livestock-producing sectors (SICs 021 through 029), the same methodology used to estimate worker population and establishment numbers in the grain sector was relied on.

Meridian based its estimates on the amount of labor required per unit of production.

Beef Cattle. It is estimated there are 34,200 employees working on 1,710 cowcalf production establishments which employ more than 10 workers. This figure is based on the estimate that it requires 7.16 hours of hired labor to produce each calf or feeder cow[7]; farmhands work an average of 157 days per year and 10 hours per day[7]; and according to the 1987 Census of Agriculture[2], there are an estimated 1,710 calf establishments that sold 2,500 or more cows each in 1987. Based on these figures, Meridian estimated that a farm employing roughly 11 employees would be capable of producing approximately 2,400 cows each year (2,400=11 employees×157 days/ year × 10 hours/day × 1 cow/7.16 hours). Because this is roughly equivalent to the base production capacity of the 1,710 farms identified by the Bureau of the Census, it is estimated there are 1,710 farms in cow-calf production establishments employing more than 10

Based on the labor required to operate large commercial feedlots it is estimated that 9,000 workers are employed on the estimated 300 feedlots likely to employ 11 or more workers. Approximately 1 employee is necessary for every 1,000 head of cattle in inventory, (based on Meridian's personal communication with a livestock commodities specialist, USDA Economic Research Service 1991). Hence, a feedlot which employs 11 or more workers is likely to have the feedlot capacity to accommodate over 11,000 cattle. Based on data from Schertz[9], 422 feedlots had a capacity

of 8,000 or more head, of these, 140 had a capacity from 16,000 to 31,999 head and 61 had a capacity over 32,000 head. From this data, it is reasonable to assume 300 feedlots have a capacity of 11,000 head or more and thus are likely to employ 11 or more workers. Because it is believed that an average of 30 workers are employed on large feedlots (representing an average feedlot capacity of 30,000 head), it is estimated that a total of 9,000 workers are employed on the 300 establishments likely to employ more than 10 workers.

Dairy Farms. Dairy farm employment and establishment estimates were derived from data reported in the 1987 Census of Agriculture[2], Agricultural Statistics 1986[5] and information from site visits by OSHA's contractor Meridian. Using a methodology based on sales, it is estimated that there are 700 dairy farms employing 10,500 workers. Meridian estimated that an average dairy farm which has more than 10 employees has sales greater than \$2 million[1]. Because the 1987 Census of Agriculture[2] does not estimate the number of dairy farms with annual sales of \$2 million or more, Meridian used data on the number of farms with sales between \$.5 and \$1 million (2,940) and the number of farms with sales in excess of \$1 million (1,457). Based on a straight line basis, it was estimated that in 1987 there were 700 farms with sales over \$2 million (1,457/2) (farms in excess of \$1 million are roughly half the farms with sales between \$.5 and \$1 million; therefore, it is assumed that farms with sales over \$2 million are roughly half the number of farms with sales in excess of \$1 million). Assuming each farm employs an average of 15 employees[1] it is estimated there are 10,500 workers employed at the 700 dairy farms which employ more than 10 persons.

Hog Farms. It was estimated by Meridian that there are currently only 10 hog farms in the United States which employ 11 or more workers each. This is based on data by Schertz[9] who estimated that there were 10 exceptional U.S. hog producing facilities (those which produce more than 30,000 head per year). It is believed that since 1979, this number has not changed because the number of farms in the 1987 Census of Agriculture[2] found in the 5,000 head plus category has not substantially increased. Based on site visit data, it is assumed that an average of 39 workers are employed at each of the large facilities. Hence, the total number of workers employed at these 10 large farms is estimated to be 390.

Poultry and Egg Producing Facilities. Because only one person-year of labor is required to produce approximately

150,000 to 200,000 broiler chickens or 50,000 to 60,000 turkeys each year[9] it is believed a poultry farm employing 11 or more workers would be capable of producing 2 million broilers annually. Data on chicken and turkey producing facilities indicate that no facilities exist in the United States which are of this size. It was determined, however, that 11 or more workers are occasionally engaged in bird catching operations at poultry farms, but that the bird catchers actually work for poultry processors (e.g., for firms such as Perdue or Holly Farms, which are classified in general industry rather than agriculture).

It is estimated that there are 15 chicken egg farms employing a total of 450 workers that fall into the scope of this study. These estimations are based on information that an egg farm employing 11 or more workers would be capable of housing half a million to several million chickens a year and would employ an average of 30 workers[9] (personal communication with poultry specialist from the North Carolina Agricultural Extension Service). Currently, there are approximately 15 such facilities in the United States. Therefore, it is believed these establishments employ roughly 450 workers (15 x 30).

From Table V-D1 the estimated number of farms and the number of workers employed in the agricultural production sector that would be affected by the proposal are shown to be 63,792 and 570,890 respectively. In addition, Table V-D1 shows the types of establishments, the number of employees and the number of establishments expected to fall under the scope of the proposed rule by primary SIC (determined by the commodity which accounts for at least 50 percent of the value of the farm's sales). In reviewing Table V-D1, it is interesting to note that the total number of farms is roughly equivalent to the total number of workers. One explanation for this is many of the small farms are operated by individuals whose major source of income is derived from non-farm activities, in which case their establishment may be classified as a farm, but they may not be classified as a farm worker. Also, nonpaid workers on farms, eg. family members, are not counted by the sources from which the estimates were derived. Affected establishments are not divided into small or large sizes because when concerned with agriculture, the proposed rule is restricted to farms with more than 10 employees. Farms with more than 10 employees are considered large farms.

Financial Profile. Financial data are not broken out for farms with more than 10 employees; however, Meridian used data profiling the largest farms as a proxy for those farms employing more than 10. Table V-D2 shows aggregate net farm income and the relative share

of total income earned by each sales class. Farms with sales in excess of \$250,000 per year, the farm category most likely to have more than 10 employees at any time during the year, accounted for 63.2 percent of net farm income in 1988.

Table V-D3 depicts average farm balance sheet data by farm sales size. In general, while debt/asset ratios are highest for the largest farms, which may indicate a weaker financial position, their return on assets is much higher than smaller farms.

Agricultural Services, Forestry, Fishing, Hunting and Trapping.
Agricultural Services include establishments in SIC 07 primarily engaged in performing soil preparation services, crop services such as cotton ginning, other animal services, farm labor and management services, and landscape and horticultural services for others on a contract or fee basis.

Forestry includes establishments in SIC 08 primarily engaged in the operation of timber tracts, tree farms, forest nurseries, and related activities such as reforestation services and the gathering of gums, barks, balsam needles, maple sap, moss, and other forest products.

Fishing, hunting and trapping includes establishments in SIC 09 primarily engaged in the catching or taking of finfish, the catching or taking of shellfish, the operation of fish hatcheries or preserves, commercial hunting and trapping, and the operation of game

reserves.

For most operations in SIC 07 through 09, OSHA's proposed rule would not

have an adverse impact. Many of these operations do not involve PEL chemicals, do not give rise to potentially hazardous exposures, or are covered by EPA regulations.

A summary of the number of establishments in SICs 07 through 09, taken from County Business Patterns[7]. is presented in Table V-D4. Forestry. fishing, hunting and trapping are considered by OSHA to be exclusive of agriculture and hence not restricted by the congressional rider restricting OSHA's jurisdiction to agricultural establishments with more than 10 persons. For this reason, the number of establishments and employees for SICs 08 and 09 under the establishments with 10 or more employees heading does not reflect the subtraction of establishments with 10 or fewer employees. Within sectors SICs 07-09, the dominant subsector is landscape and horticultural services (SIC 0781, 0782, and 0783). Estimates of the number of establishments and employees potentially affected by the proposed rule are presented in Table V-D5. As

indicated on Table V-D5, approximately 10,000 establishments and 218,172 employees are likely to be affected by the proposed rule. Total annual payroll for these establishments is nearly \$2.7 billion, or an average of \$270,000 per establishment. Financial information on agricultural services and forestry was compiled by Meridian from Dun and Bradstreet's Industry Norms and Key Business Ratios[10] to give a general overview of the entire industry (data on 0831, Forest Nurseries and Gathering of Forest Products, were not available). Financial data for fishing, hunting and trapping was gathered from Dun and Bradstreet's Industry Statistics and Financial Analysis[11]. These 1989 data do not include all establishments within the industry, but instead represent only a sample. Table V-D6 presents totals for reporting firms within each four-digit subgroup. Fishing, hunting and trapping has the largest return on assets (16.5%). followed by cotton ginning (11%) and lawn and garden services (10.7%).

TABLE V-D4.-NUMBER OF AGRICULTURAL SERVICE AND FORESTRY ESTABLISHMENTS IN 1987, BY SIC

1 USDC, 1990 County Business Patterns, specifies its employment category as 10 or more rather than more than 10. No adjustment was made for this anomaly; thus the estimated number of establishments employing more than 10 may be slightly inflated.

2 Establishments and employees in SICs 08 and 09 have traditionally been considered by OSHA to be outside of the agricultural sector. Establishments and employees in these SICs fall completely within OSHA's jurisdiction and are not subject to the congressional rider on OSHA's appropriations.

Summary

Combining agricultural production. agricultural services, forestry, fishing. hunting and trapping estimates, OSHA calculates that a total of 73,751 establishments are potentially affected by the proposed standard (Table V-D5). This total is strictly for large establishments (farms employing more

than 10 workers) 1 which make up roughly 3.4% of all U.S. farm operations in SICs 01-09. The total population at risk is an estimated 789,062 employees (Table V-D5) which constitute 28% of all workers in SICs 01-09. Three major groups could be affected by the proposed rule. These groups are SIC 01-agricultural crop production; 02agricultural livestock production; 07-

agricultural services. Forestry, fishing, hunting and trapping may also be affected. Industry segment SIC 01, Agricultural Crop Production, is the largest affected sector; over 58,457 establishments and 498,350 employees. This seems reasonable in light of the fact that this segment is the most labor intensive segment of all the SICs.

2. Employee Exposure and Benefits

Introduction. Employee exposures to the substances included in the scope of this rule making are associated with a wide variety of acute and chronic conditions and illnesses. These include sensory irritation, narcosis, organ system dysfunction, chronic respiratory disease, neurological impairment, allergic sensitization, and cancer. OSHA believes that reducing worker exposures to such substances by applying limits where none existed previously will result in significantly reduced levels of exposure and disease. Section I-F of this preamble provides additional discussion of exposures in agriculture.

This chapter describes both the methodology used to identify workers potentially exposed to the hazardous substances included in this rule making and the expected benefits to those workers resulting from the application of permissible exposure limits to the agricultural sector.

Methodology. The diversity of agricultural work places, the large number of substances included in the proposed rule making, and the variety of operations and processes in the agricultural sector required Meridian, OSHA's contractor, to develop a methodology to permit the identification of (1) non-pesticidal hazards ² regulated by OSHA that are of concern in the agricultural environment, (2) the number of workers employed on large farms exposed to these hazards, and (3) the magnitude of their exposures to the substances of concern.

Meridian, OSHA's contractor for this project, relied on the professional judgment of experts in the agricultural field to identify specific processes and operations widely recognized as presenting non-pesticidal toxic-substance exposure hazards to agricultural workers. Hazardous processes in the following industries were identified:

Silo Operations

· Cotton Ginning

· Grain Handling (Post-Harvest)

Grape Harvesting

For some operations, preliminary investigation revealed that the exposures of concern fell outside the scope of this project, either because the problem was the result of a pesticidal use of a toxic substance (as was the case with the mushroom industry), because it was related largely to a confined-space problem (as was the case with silo gases) or due to the fact

that problematic exposures primarily occur on farms with fewer than 11 employees (as was the case with swine confinement and poultry operations and many other agricultural operations). OSHA requests that any information on exposures not identified by this methodology be submitted to the public record of this standard for review.

Description of Data Sources Used. To derive a baseline of current exposures and to assess the quantitative benefits associated with reducing those exposures, the following data sources were used:

- · OSHA compliance case files
- · NIOSH Health Hazard Evaluations
- Agriculture extension agents in 10 of the major agricultural states.
- The Institute of Agricultural Medicine at the University of Iowa
- Agricultural economists at DPRA, Meridian's subcontractor
- · The USDA library in Beltsville, MD
- OSHA's Integrated Management System (IMIS)
- Discussions with industrial hygienists at the Department of Labor and Industries, Washington State
- Discussions, observations, and exposure measurements from Meridian's site visits
- Discussions with experts at USDA's Research Unit and with individuals at the California Department of Food and Agriculture

² Currently the Environmental Protection Agency has jurisdiction over the application and use of pesticides pursuant to an EPA label. However, OSHA has authority over the non-pesticidel use of pesticide chemicals, use not permitted by the label or when farmers make their own pesticides. Benefits from these activities are not covered in this analysis.

⁸ In a study by Morris, Lenhart and Service published in the February 1991 American Journal of Industrial Medicine, It was determined that 86 percent of chicken catchers reported at least one acute respirator symptom associated with work in poultry bouses. Although these chicken catchers do not fall into the scope of the proposed standard, they are employed by general industry firms and are already subject to PELs, their exposures give an indication of respiratory problems occurring on all farms in the poultry confinement industry; an industry which is not analyzed in this study because no poultry confinement establishment is large enough to employ 11 or more workers.

Estimates of the Number of Potentially **Exposed Employees**

Silo Operations (SICs 0212, 0214, 0219,

Exposure. Agricultural workers who work in and around silos are exposed to the dust that is generated by the movement of the silage during the loading and unloading of silos. In a study conducted by May[1], employee breathing zone samples for total and respirable dust were collected during five silo operations. The respirable dust exposures of employees working at three of the five silos ranged from 0.3 to 1.4 mg/m3, significantly less than the 5 mg/m3 PEL. In the fourth silo, two personal breathing zone samples showed respirable dust exposures of 10.1 and 10.5 mg/m³, both greater than the 5 mg/m³ PEL. At the fifth silo, the respirable dust exposures of two employees were measured as 24.6 and 40.3 mg/m³, respectively. Total dust measurements taken inside the chute using area sampling were less than 15 mg/m3 in three silos. In the fourth silo, total dust concentrations ranged from 13.5 to 25.2 mg/m3. Seven area samples for total dust were collected at the fifth silo, all of which exceeded the 15 mg/m3 PEL; these samples ranged from 86.8 to 154 mg/m3. These data indicate that some silo workers are exposed to respirable dust in excess of OSHA's 5 mg/m3 PEL for respirable dust and the 15 mg/m3 PEL for total dust; two fifths of the silo operations studied had respirable dust levels resulting in overexposure to all of their employees. Therefore, it is assumed that 40% of all persons employed at silo operations are overexposed to total and respirable dust. (Only two employees at any one time are needed for the silo operation; however, because hired farm hands participate in all aspects of a farm's activities, it was assumed that each farmhand will be involved in silo operations during their employment.)

Population at Risk. To estimate the number of silo workers potentially exposed to dust during silo unloading operations, sectors using silage as winter feed were identified. Based on observations and discussions during site visits, Meridian assumed that silos are present in both of the following industries: SIC 0212, Beef cattle, except feedlots and SIC 024, Dairy cattle. It was believed that silos are not likely to exist at cattle feedlots, poultry operations and hog farms because both use a highcalorie mixture of grains and other ingredients to achieve rapid weight gain in animals.

Exposures to Dust at Cattle Establishments. Data presented in chapter II indicate that there are roughly 1,700 beef cattle, except feedlot, establishments (SIC 0212) employing more than 10 workers and that these establishments have a total employment of 34,200 employees. No data are available to determine how many of these workers are actually exposed to dusts; it was assumed that all of these workers are potentially exposed to dusts during their employment.

Exposures to Dust at Dairy Farms. Meridian estimated that there are 700 large dairy farms employing 10,500 workers in the United States (see Table V-D1, chapter II). Although no data exist to indicate how many of these farms actually have silos, it is assumed that all of the establishments are likely to have silos and that all of the 10,500 employees at these establishments are potentially exposed to the hazards associated with silo operations.

Summation of Exposures for Silo Operations. Based on the estimates above, it is believed a total of 44,700 workers are exposed to silo-related hazards in 2,400 establishments that employ more than 10 workers. Due to personal exposure data reported by May[1] Meridian estimated that two fifths or 40 percent of these facilities and workers (960 and 17,800 respectively) are currently exposed above OSHA's 5 mg/m3 PEL for respirable dusts. It is likely that these workers are also exposed above OSHA's 15 mg/m3 PEL for total dust since it is unlikely that the respirable mass fraction of this dust represents a substantial fraction of the total dust mass.

Cotton Ginning (SIC 0724)

Exposure. Cotton ginning is seasonal and operations potentially expose workers to cotton dust, pesticide residue 4 and particles not otherwise classified (PNORs), i.e. nuisance dust. Two NIOSH publications describe employee exposures to these substances. One of these studies is a Health Hazard Evaluation describing three cotton gins in Arizona[2] in which cotton dust measurements and personal samples for total airborne particulates were taken. The study concluded that employees working at the gin stand and bale press were exposed above 1 mg/m3 for cotton dust (this is roughly equivalent to the 500 µg/m³ vertical elutriator [VE] PEL OSHA is proposing). In contrast, these data do not suggest that cotton gin employees are exposed above OSHA's 15 mg/m3 PEL for total

dust (PNORs). In addition, NIOSH analyzed bulb cotton samples taken from various process locations for pesticide residues, including residues of the Table Z-1-A substances monocrotophos and methyl parathion. The analysis of bulb samples revealed detectable levels of monocrotophos and methyl parathion residues on the bulk samples; however, the data as reported do not permit an assessment of the levels of employee exposure to these substances.

The second publication concerned with cotton dust exposure is an extensive study of worker exposure to cotton dust during ginning operations. It was conducted by NIOSH[2] and included cotton dust measurements taken at 35 gins located in five different regions of the country. For each cotton gin, NIOSH reported the geometric mean and geometric standard deviation of cotton dust levels. These exposure profiles were analyzed by Meridian along with exposure distributions reported by Zey[3]. The latter studies findings suggest there is a 10-percent average probability that a cotton dust measurement will be found to exceed the 1 mg/m 3 (500 μ g/m 3 VE) PEL for cotton dust.

Population at Risk. During the 1986-87 season there were 1,162 cotton gins in active operation[4]. According to Zey[3], a typical cotton gin has three or four gin stands and roughly 11 production workers. Meridian estimated that 12,782 workers (1162 gins x 11 estimated workers per gin) are potentially exposed to cotton dust, pesticide residues, and total dust (PNORs). In the study conducted by Zey, a 10-percent average probability that a cotton dust will be found to exceed the 1 mg/m3 PEL was estimated. Therefore, OSHA estimates that 10 percent of the estimated 12,782 cotton gin workers, or 1,278 employees are currently exposed above OSHA's proposed limit for cotton dust. Based on the exposure data reported in the NIOSH HHEs, it is believed that none of these employees are currently exposed above OSHA's 15 mg/m3 PEL for total dust(PNORs). As explained above, the data contained in these HHEs describing levels of pesticide residues is not suitable for estimating the pesticide levels to which employees are exposed. Hence, no estimate can be derived for pesticide residue exposure.

Post-harvest Grain Handling Operations (SICs 011, 0711, 0721, 0722, 0723 5).

⁴ The residues of pesticides listed on Table Z-1-A is not a situation covered under EPA's FIFRA and is therefore considered to fall within the scope of this

It should be noted that SIC 0723 (crop preparations for market except for cotton ginning) is

Exposure. Most of the data describing employee exposures to dust during grain handling operations are relevant only when looking at large grain elevator operations, which are not within the scope of OSHA's present rule making (these elevators are classified in SICs 4221 and 5253 and were addressed by the 1989 Air Contaminants standard for general industry). There are no data that adequately describe the dust exposures of workers during grain handling operations at agricultural facilities classified in SIC 011 (Cash Grains). However, it is believed that these exposures can be approximated on the basis of data that describe the dust exposures of workers during the loading of trucks at small grain elevator facilities. Burg[5] studied such an operation and reported that the dust concentrations (as determined from personal air samples) were 15.3, 145, and 2,346 6 mg/m3 during the loading of trucks with corn; because corn is not as dusty as wheat, oats and other grains it is believed that the exposure potential represented by corn dust somewhat underestimates dust exposures typically encountered by workers during operations that involve the transport and handling of wheat, oats and other grains usually found in storage bins located at agricultural facilities. It is estimated that grain handling often

causes dust exposures that exceed OSHA's 10 mg/m³ PEL for grain dust (applicable to the handling of oats, wheat, and barley) and the 15 mg/m³ PEL for total dust (applicable to dust arising from all other types of grain).

Population at Risk. The loading and unloading of grain from storage bins is not generally a labor-intensive operation. Therefore, it is assumed that no more than one or two employees at each grain farm are involved in these operations and are thus exposed above the OSHA PELs for grain dust or total dust(PNORs); this would mean approximately 864 farm workers (average # of persons x 578 establishments) at the 576 grain farms estimated to have more than 10 employees (see Table V-D1). According to the 1986 Agricultural Statistics[6], the production of wheat, oats, and barley constituted 25 percent of total 1985 U.S. grain production; it is therefore believed that 216 or 25 percent of the estimated 864 workers engaged in grain handling operations are currently exposed above OSHA's 10 mg/m3 PEL for grain dust and that the remaining 75 percent (or 648) are currently exposed above OSHA's 15 mg/m3 PEL for total dust.

Grape Harvesting (SIC 0172)

Exposure. There is a potential for exposure to inorganic dusts, including

free silica, which are released when foliage on the vine is disturbed during harvesting of grapes. After the spring rains, soil dust that is generated during the cultivation of the crop accumulates on the leaves of the plant; this accumulation continues throughout the drier summer until harvest time, when the dislodgeable portion of the dust is released into the air by the harvesting operation. The amount of dust released at harvest time depends on the specific crop and the local weather conditions prevailing at the time of harvest. Because grape crops require extensive cultivation regardless of where they are grown, workers harvesting grapes anywhere in the country are potentially exposed to airborne dust. In addition, because grapes are typically grown in areas having sillicacious soil (i.e., rocky or sandy soil), grape workers are potentially exposed to free silica.

In a California study by Popendorf and Spear[7], average personal total dust exposures of 13.5 mg/m³ for grape pickers were reported. Another study by Popendorf[8] indicated that a substantial fraction of the grape picker population is exposed to dust levels that exceed both OSHA's 15 mg/m³ PEL for total dust (PNORs) and its .1 mg/m³ PEL for respirable crystalline silica. Data from these studies can be seen in Tables

V-D7 and V-D8.

Table V-D7.—SUMMARY OF WORKER EXPOSURES TO TOTAL DUST AND RESPIRABLE SILICA DURING GRAPE HARVESTING

	Стор	Numbe of tota dust sample taken	Number of facilities surveyed for total dust	Percent of total dust samples exceeding 15 mg/m³	Percent of respirable dust samples exceeding 1 mg/m³ of free silica *

Grapes (SIC 0172)	8,873*	75	6,655 (8873×.75)	60	5,324 (8873×.60)

^{*} Total for the United States (excluding California).

^b Data from Popendorf et al. (1982). Source: Meridian Research Inc., Table 3–6[10].

covered by a settlement agreement between OSHA. the National Food and Grain Association (NFGA)

and the AFL-CIO which retains the 10 mg/ms limit but permits use of respirators in certain operations.

Out of 74 observations, 2,346 was the highest recorded exposure, 813.1 and 176.1 were the next highest exposures.

Population at Risk. To estimate the size of the potentially exposed population, it was assumed that all grape pickers in the U.S. are conceivably exposed to total dust (PNORs), as well as to respirable free silica. According to the 1987 Census of Agriculture[9], grape farms (SIC 0172) constitute approximately 13 percent of all fruit and tree nut facilities in the United States. Assuming that the proportion of large fruit and tree nut establishments producing grapes is the same as that for all fruit and tree nut establishments, it is estimated that there are 1,495 large grape producing establishments (11,375×13 percent) employing 11,830

workers (91,000×13 percent). No data on the proportion of the work force actually engaged in the harvesting of grapes were available; however, because most of these workers are likely to be involved in grape harvesting, it was assumed that 75 percent of the work force, or 8,873 workers, are potentially exposed to total dust and respirable silica during grape harvesting.

Estimates of the number of grape workers who are currently exposed above OSHA's PELs for respirable silica and total dust were derived from the employment estimates presented above and from the exposure data reported by

Popendorf[8]. The derivation of these estimates is presented in Table V-D8 which shows that 6,665 workers [8,873×.75] are currently exposed above OSHA's PEL for total dust of 15 mg/m³ and 5,324 (8,873×.60) are exposed above the .1 mg/m³ PEL for respirable silica during the harvesting of grapes (Table V-D8).

Summary. Table V-D9 presents a summary of employees at risk of overexposure. There are an estimated 32,000 employees (some workers may be double counted) on 5,643 farms who are at risk of exposure to substances included in this rule making.

TABLE V-D9.—SUMMARY OF EMPLOYEES AT RISK OF OVEREXPOSURE

Activity	Industry	Substances	No. of establishments	Estimated population at risk
Silo Operations	SIC 0212: Beef cattle, except feedlots		2,410	17,880
Cincina	SIC 024: Dairy cattle			4 070
Ginning		Grain dust (10 mg/m³)	1,162 576	1,278
	Old of 7. Cooling and	Total particulate (15 mg/m³)		648
Harvesting Grapes	SIC 0172: Grape harvesting		1,495	6,655 5,324
Total	5,643	32,001		

Employee Benefits. In addition to estimating the number of employees exposed to the substances in this analysis, OSHA also estimated the number of employees who are at risk of experiencing particular types of adverse health effects. To conduct this analysis, each substance in which overexposure was determined, was assigned to a health hazard category; these assignments were based on the primary health effects expected from reducing a previous limit or establishing a new limit for a particular substance. In the benefit analysis described below. substances were classified according to their primary health effect and the operations in which they were present. When direct health effects evidence was not available, analogous chemicals were used to develop benefit estimates. OSHA believes that farm workers may be exposed to other air contaminants, such as CO2, solvents and fertilizers, which were not identified in this analysis due to the limited data available concerning agricultural exposures. As a result, benefits for the reduction of these exposures were not quantified even though OSHA believes some unspecifiable benefits will result.

OSHA's contractor, Meridian Research Inc., developed an approach that relied on substance-specific toxicologic information that quantitatively related exposure to prevalence of disease for the specific substances of interest. It did not rely on general statistical data describing the illness mortality and morbidity experience of agricultural workers for two principal reasons. First, general illness mortality and morbidity rates reflect disease risks that are associated with exposure to a number of substances that are not generally covered by this rule making action, notably pesticides, herbicides. insecticides, fungicides, defoliants and disinfectants. (It should be noted however, that activities where a pesticide was misused according to its EPA label or where farmers make their own pesticides are instances covered by OSHA. OSHA has not been able to quantify benefits from the regulation of these instances but believes benefits will result in the form of some reduction in illnesses.) Second, such statistics reflect the health experience of farmers who work on small farms (i.e. those with 10 or fewer employees), which together employ most of the agricultural workers

in the United States. In order to avoid the problem of using under-representative data, a substance-specific approach using toxicologic information relating quantitative exposure to prevalence was adopted. Substances, and the agricultural operations in which occupational exposures have been documented, include exposure to: silage dust during silo unloading operations; respirable silica during grape harvesting; grain dust during grain handling operations; and cotton dust during cotton ginning operations.

Silage Dust

The principal health hazard associated with excessive exposure to silage dust is a condition known as organic toxic dust syndrome, an illness in which the affected individual suffers fever, malaise, headaches, and chest tightness[3]. In a study conducted by May[3], exposures to silage dust generated by unloading operations in five vertical silos were analyzed and found to exceed OSHA's 5 mg/m³ PEL at one of the five silos. Assuming the survey is representative of current industry conditions, such exposures may be expected to occur among roughly 20

These calculations exclude California.
Currently, CAL-OSHA enforces PELs in agriculture

which are stricter than OSHA's proposed PELS. For this reason, Californian establishments and

employees were excluded from the population-atrisk estimate.

percent ⁸ of the workers engaged in silo unloading operation with sufficient magnitude (more than 5 times the PEL) to cause symptoms of organic toxic dust syndrome at least once during the silo unloading season.

There is no evidence that organic toxic dust syndrome is likely to occur when exposures to respirable dust conditions are maintained at or below the 5 mg/m³ PEL[3]. Therefore, it is estimated that compliance with OSHA's 5 mg/m³ will result in the prevention of at least 8,940 cases of organic toxic dust syndrome (44,700 silo workers × 20 percent) per year. Based on the severity of symptoms caused by organic toxic dust syndrome (OTDS), OSHA

estimates that 25% of all OTDS cases (roughly 2,235 cases) will result in lost workdays.

Respirable Silica

Exposure to respirable dusts is known to cause silicosis, a fibrotic lung disease that can severely compromise pulmonary function. In a study conducted by Popendorf in 1982[8], it was determined that respirable silica exposure frequently exceeds OSHA's 0.1 mg/m³ PEL, usually averaging 0.15 mg/m³ during grape harvesting. Calculating the lifetime cumulative-silica exposure of the worker populations, Meridian estimated that about two percent of grape harvesters who are overexposed

to respirable silica are likely to develop reduced pulmonary function as a consequence of exposure. This corresponds to a population of 106 grape harvesters (2% of the 5,324 workers estimated to be overexposed to respirable silica) at risk of acquiring silicosis. Meridian states in its report that through the use of approved dust masks having a protection factor of 5 (see Chapter VI), the risk of acquiring silicosis will be reduced to less than one percent. (Meridian used a methodology where average silica exposures were translated into the number of dust years exposed in order to define the current incidence level. Using the formula:

Number of dust-years exposed 9 =

Average Silica Exposure

0.05 mg/mg3

No. days/year exposed

365

And assuming grape harvesters work an average of about 20 years and that these workers are exposed to respirable silica over an average of 40 days per year during grape harvest, Meridian calculated that grape harvesters who are currently exposed above OSHA's PEL for respirable silica accumulate approximately 6.6 dust-years of exposure to silica over their working lifetime. Applying this information to a dose response curve[11] between granite dust and quartz [both silicacious substances] versus pulmonary forced vital capacity, Meridian was able to determine that two percent or 106 harvesters over a 20 year working life were at risk of acquiring silicosis in grape harvesting.) Therefore, it is estimated that compliance with the 0.1 mg/m³ PEL will prevent pulmonary function reduction in approximately 106 grape harvesters over a 20-year working life (an average of 6 cases avoided per year). Based on the severity of symptoms caused by silicosis (silicosis can result in death). OSHA estimates that all of the cases will result in lost workdays.

Grain Dust

The respiratory and other effects of exposure to grain dust are varied and include both acute and chronic abnormalities. Workers exposed to grain dust frequently experience symptoms of cough, expectoration, wheezing and chest tightness; these symptoms may result from either an acute exposure or may reflect the development of chronic bronchitis from prolonged exposure. In addition, grain workers experience episodes of "grain fever", which occurs during or several hours after exposure.

As a result of a study conducted by Rankin[12], Meridian determined that workers exposed in excess of OSHA's 10 mg/m3 PEL for grain dust during the unloading of storage bins containing oats, wheat and barley are likely to experience adverse respiratory symptoms (Table V-D10). Because the workers are generally exposed to levels exceeding 15 mg/m3, it was assumed that the prevalence of respiratory symptoms in this group parallels that of the highest group studied by Rankin where prevalence for cough, expectoration, dyspnea and eye irritation was 89, 67, 44 and 44 percent,

respectively. Assuming the prevalence for cough, expectoration, dyspnea and eve irritation in grain workers is the same as the group studied by Rankin it is believed that as a result of complying with OSHA's 10 mg/m3 PEL for grain dust and 15 mg/m3 for total dust, the prevalence of respiratory symptoms among these workers would fall to the same levels experienced by Rankin's 5-10 mg/m3 and 10-15 mg/m3 exposure group.10 Hence, the anticipated reduction for cough, expectoration, dyspnea and eye irritation is expected to be 49; 14; 3; and 11 percent for those over exposed to grain dust and 22; 0; 0 and 0 percent for those over exposed to total dust. After applying these reductions in symptoms to the estimated 216 farm workers (Chapter 3) who are currently overexposed to grain dust and the 648 over exposed to total dust, it is estimated that coughing, expectoration, difficulties in breathing, and eye irritation will be avoided in 236, 30, 80, and 24 workers respectively. Based on the mild severity of the symptoms caused from over exposure to grain dust, it is estimated that none of these cases will result in lost workdays.

^{*} While 40 percent or two fifths of all employees at silo operations are overexposed, 20 percent of all employees are exposed at a level (roughly 5 times

the PEL) high enough to cause organic toxic dust syndrome.

This formula relies on the concept of dust-years of exposure defined by Therialt, Buress,

DiBernar.lini, et al. in their 1974 study and by Peters in his 1986 paper.

¹⁰ The 5-10 mg/m³ group had roughly the same prevalence rates as the 0-5 mg/m³ group which is not presented in table V-D10. Thus, although it is probable that exposures will be lowered below 5 mg/m³ due to the use of respirators, there will be no further decline in prevalence.

TABLE V-D10.—SUMMARY OF THE PREVALENCE OF RESPIRATORY SYMPTOMS EXPERIENCED BY GRAIN DUST WORKERS, BY EXPOSURE LEVEL

Range of exposure level (mg/m³)	Prevalence of respiratory symptoms (percent of workers studied)*				
	Cough	Expectoration	Dyspnea	Eye irritation	
5-10	40 67 89	53 67 67	7 50 44	33 50 44	

^{*}Data reported only for those symptoms for which the prevalence in the high exposure group was significantly different from that in an unexposed control group.

Cotton Dust

Byssinosis is the general term applied to acute and chronic respiratory disease caused by excessive exposure to textile vegetable dusts, which include cotton, flax and hemp fibers. As the disease worsens, affected individuals experience chest tightness and/or breathlessness both on return to work and on subsequent days and show decrements in pulmonary flow that become progressively more pronounced; at this stage, a clear picture of chronic obstructive lung disease can be seen. In a study conducted by Zey among 521 non-smoking cotton gin workers employed in 37 gins [3], an exposurerelated increase in the prevalence of chronic bronchitis symptoms and textile vegetable dust disorders was discovered. Using regression analysis. Meridian constructed a mathematical expression relating exposure to prevalence of these disorders.

To estimate the potential benefits associated with promulgation of the 500 μg/m³ VE cotton dust PEL in cotton gins. Meridian assumed that the 1,278 workers who are overexposed to cotton dust are exposed to an average TWA concentration of 1.5 mg/m3 (overexposures generally occur in the range of 1.1 to 2.0). Meridian also assumed that cotton gin workers work an average of 20 years in gins. Using the exposure-response relationships, (Exhibit 5-4 [10]) Meridian estimated that the current prevalences of chronic bronchitis and textile vegetable dust disorders among the 1,278 workers estimated to be overexposed are 28 and 43 percent respectively. By reducing these workers exposures to the 500 µg/ m³ VE PEL, OSHA estimates prevalence will be reduced to 17 percent for chronic bronchitis (i.e. a reduction of 11 percent) and 24 percent for textile vegetable dust disorders (i.e. a reduction of 19 percent).11 This analysis suggests that

the promulgation of the 500 µg/m3 PEL for cotton dust in cotton ginning operations will prevent symptoms of chronic bronchitis from developing in 141 workers (1,278×11 percent) and symptoms of textile vegetable dust disorders in 243 workers (1,278×19 percent) over a 20 year working life. Hence, promulgation of the final rule will prevent chronic bronchitis from developing in approximately 7 workers (141/20), and textile vegetable dust disorders in roughly 12 workers (243/20) each year. Chronic bronchitis is a potentially crippling disease, greatly reducing the quality of life and the productivity of its victims, OSHA estimates that all cases of chronic bronchitis will result in lost workdays. No cases of textile vegetable dust disorders are expected to result in lost workdays.

Summary of Benefits and Exposure. As is evident, agricultural workers are exposed to a variety of air contaminants in a number of different operations. It is estimated that over 17,800 workers are overexposed to total dust as well as respirable dust in silo operations; 1,278 employees are currently overexposed to cotton dust in cotton gins; 216 workers are exposed above OSHA's PEL for grain dust and 648 are exposed above OSHA's PEL for total dust during postharvest grain operations; 5,324 grape harvesters are overexposed to respirable silica; and 6,655 workers are overexposed to total dust during grape harvesting.

The benefits presented in this chapter show that the proposed rule is necessary and that it will provide quantifiable benefits to the agricultural community. As a result of the promulgation of this rule, 8,940 annual occurrences of febrile organic toxic dust syndrome will be prevented; 5 silica-induced pulmonary function declines will be eliminated

each year; acute respiratory symptoms occurring in 24 to 106 workers will be avoided annually; and 7 cases of chronic bronchitis as well as 12 cases of textile vegetable dust disorders will be prevented annually. OSHA estimates that 2,248 (24%) of these cases will result in lost workdays while 7,090 (76%) will be non-lost workday cases.

3. Assessment of Nonregulatory Alternatives

For a full discussion on the need for and the appropriateness of a regulatory solution to address occupational exposures to air contaminants, see section V.B.4. of this preamble.

4. Technological Feasibility

Introduction. This chapter presents a technological feasibility analysis of the agricultural sector's ability to meet OSHA's proposed permissible exposure limits (PELs) for a wide range of occupational health hazards. These PELs include limits on airborne concentrations of substances, and in some cases, direct contact on the skin with the substance.

The control of workplace exposures to toxic chemicals involves combining a variety of standard techniques to solve a situation-specific problem. For a variety of situations where air contaminants are encountered by workers in agriculture, compliance can be achieved by applying known engineering control methods. In addition, work practice improvements and personnel protective equipment usage may also be required.

This chapter examines the feasibility of engineering controls, work practices and personal protective equipment needed to reduce workers' exposure levels to total dust, respirable dust, cotton dust and respirable silica.

Types of Controls

Engineering Controls. Engineering controls involve the use of local exhaust ventilation, general ventilation, isolation of the worker, enclosure of the source of emissions, process modifications, equipment modifications, and substitution of non-hazardous chemicals. These methods may be used alone or in combination of any two or more controls depending upon the needs of a specific situation. Variations in situations usually result from the type of process being used and the number of chemicals in the air. However, these controls are considered standard techniques which will effectively control these variables either by themselves, or coupled with changes in work practices.

Ventilation. Perhaps the most widely used technique for controlling chemical exposures is the use of ventilation.

General ventilation uses the movement of air within the general work space to displace or dilute the contaminant with fresh outside air. General ventilation is not typically the preferred control method in most operations due to the large volumes of air movement required. Local exhaust ventilation uses much smaller volumes of air, exhausted from the point at which contaminants are generated to remove the contaminant at the source.

Work Practices. Work practice controls include housekeeping procedures, material handling procedures, training and personal hygiene. In many cases, it is possible to bring about substantial reductions in employee exposures by applying work practice controls. A work practice control could be as simple as keeping a distance from a source of emission.

Personal Protective Equipment.
Where it is impractical to apply
engineering or work practice controls, or
where their application will not
consistently reduce employee exposures
below the proposed PELs, personal
protective equipment such as
respirators, may be required in order to
prevent or reduce exposures.

Feasibility. This chapter presents examples of feasible methods for controlling exposures to hazardous substances encountered in processes used in the SICs for which costs (Chapter VI) and benefits (Chapter 3) have been identified. Unit costs for these controls are used as the basis for the cost projections in Chapter 5.

Feasibility determination is made for the following operations which have been identified as having activities which result in overexposure to certain hazardous substances:

Silo operationsCotton ginning

Post-harvest grain handling operations

· Grape harvesting

Silo Operations. Employee exposures to silo dust occur when workers unload silage to feed animals during the winter months. These exposures result from dust generated by silage falling down the silo chute into a truck or onto a conveyor for subsequent transport to the animal feed area. Dust exposure may also occur when employees climb up the chute and enter the silo to maintain or repair the silo's automatic loading device.

The exposure data presented by May[1] and described in Chapter III

indicate that employee exposures to dust exceed the 5 mg/m³ PEL for respirable dust about 40 percent of the time during silo operations. It is believed, by OSHA's contractor, that the 15 mg/m³ PEL for total dust is also exceeded at these times.

Feasibility Assessment. At present, no controls are in place in silos to reduce worker exposures to dust. The implementation of a simple work practice, such as training workers to stand upwind during unloading, would reduce dust exposures to some extent, although the percentage of reduction achievable by this approach is not known. Wetting, a commonly employed dust suppression technique, cannot be used with silage because wetting would interfere with the flow of silage during unloading and would also promote spoilage. Ventilation, another common technique for controlling airborne particles, and the only engineering control applicable to this situation, cannot be configured for such a large area and could even create more of an exposure problem in this particular environment. Reliance on disposable dust respirators is seen as a practical approach to achieve compliance with the PELs for respirable and total dust during silo operations.

Cotton Ginning

Feasibility Assessment. Based on NIOSH's extensive 35-gin survey[2], 86 percent of all gins are already achieving mean employee cotton dúst exposures at or below the 500 µg/m3 level most of the time. These data demonstrate that compliance with the 500 µg/m3 cotton dust PEL is technologically feasible for the cotton ginning industry and is already being achieved by most ginning operations at the present time. Nevertheless, it was estimated in Chapter III that 10 percent of the ginning workforce, or 1,278 employees, continue to be exposed above the PEL. The exposures of most of these workers are within a factor of 2 of the PEL; in a few rare cases, however, overexposures may exceed the PEL by a factor of 6[3].

Based on these data, there is no issue of technological feasibility for facilities in this sector, since the overwhelming majority of ginning operations are already well below the cotton dust PEL. For those few facilities still above the PEL, OSHA's contractor, Meridian, concluded the implementation of simple housekeeping measures will achieve the 1 mg/m³ PEL. Meridian's reasoning was based on the following: The exposure data presented by Zey[4] and described in Chapter III strongly suggest that employee exposures to cotton dust can

be maintained below 1 mg/m3 by applying consistent work practices[4]. The authors report that "The accumulated thrash inside the plant[s] [is] inevitably a secondary source of airborne dust"[4]. Second, NIOSH reports that the dust raised during the dry sweeping of facilities is responsible for the dustiest conditions in these gins[2]. And lastly, the Zey[2] data show that at least one of the readings taken in half of the 35 gins examined were above 1 mg/m3; however, these high readings were infrequent, occurring only in about 10 percent of the cases overall. It is Meridian's opinion that this pattern of infrequent high particulate exposures is consistent with the failure of work practice controls rather than with inadequate engineering controls (which would be reflected in plant-wide high readings). In other words, NIOSH's finding that employee exposures to cotton dust exceed 1 mg/m3 on an infrequent basis in many cotton gins suggests that work practices, such as the regular cleaning of work areas and equipment, are being applied in an inconsistent manner or are being performed improperly by those facilities having high readings.

Post-Harvest Grain Handling Operations. Employee exposures to grain dust during post-harvest grain handling occur during the transfer of grain from storage bins to trucks[5], and the exposure data presented in Chapter III show that these exposures range from 15.3 to 2,346 12 mg/m3. These data were derived from personal samples taken on the operator, who was standing on top of a truck directing the flow of grain from a chute that dropped grain into the truck from a distance of several feet. The actual 8-hour TWA exposure of the employee sampled by Burg[5] is difficult to gauge because the duration of the sampling and the employee's pattern of exposure were not described in the Berg article. Because this employee was not reported to be wearing respiratory equipment during the unloading operation, it is believed that the employee's exposure did not exceed a few hundred mg/m3 as an 8-hour TWA; exposures higher than approximately 200 mg/m3, if sustained over a full workday, would cause considerable discomfort in the absence of respiratory protection. Therefore, it is believed the 8-hour TWA dust exposures of workers during bin unloading operations are unlikely to exceed about 200 mg/m3.

Feasibility Assessment. Meridian's final report states that compliance with

Grape Harvesting

Feasibility Assessment. Unlike the harvesting of grain and other crops, the harvesting of grapes is primarily a manual activity. Workers are potentially exposed to total dust and respirable silica in these operations at levels in excess of OSHA's PELs for these substances (see Chapter III). Some reduction in dust exposures could be achieved in instances where it is possible to wet the fields and vines prior to picking; however, this procedure is not feasible in the majority of cases because crop spoilage increases if the fruit is picked and packed wet. Therefore, it is believed that the owners of these farms will rely on respiratory protection (NIOSH approved dust masks) to reduce their employees' exposures to total dust to the 15 mg/m3 PEL and to respirable silica to the 1.0 mg/m3 PEL.

Engineering controls such as ventilation, oil conveyors and pneumatic dust control mechanisms have proven effective in controlling grain dust in other sectors involving grain handling. It is possible that these controls could be used for post-harvest grain handling. However, OSHA's contractor, Meridian, has reviewed some dust control systems and found that they may not be effective in the open areas post-harvest grain handling takes place in and may even cause additional problems by increasing the level of grain dust in the air. As a result, Meridian has recommended to OSHA that some workers may be required to wear respirators some of the time as part of their duties.

Summary. Based upon the analysis in this chapter and the supporting documentation, OSHA believes that

controlling exposures on large agricultural establishments to substances found on the Z-Table is technologically feasible through the use of engineering controls, work practices and personal protective equipment. OSHA believes that these controls will be effective in reducing routine exposure to the substances posing a threat to worker health on these agricultural establishments.

5. Costs of Compliance

Introduction. Costs are related to recommended engineering controls, work practices and personal protective equipment needed for specific processes in order to maintain workers' exposures at or below the levels specified in the proposed standard. Given the large number of substances being regulated, an assessment was required that would examine a large number of operations over the entire agricultural sector.

Work practice requirements were identified by industrial hygienists based on their experience and research on operations and exposure situations in each operation. Also, included in the cost calculations are costs for all equipment required for exposure control. These latter costs were developed on a per person basis. Capital costs for HEPA vacuums and full facepiece respirators were annualized over 5 years using a 10 percent cost of capital and adding annual operating and maintenance costs estimated at 10 percent of the capital cost.

An annual cost was developed for each operation. These costs are

OSHA's 15 mg/m3 8-hour TWA PEL for total dust and with OSHA's 10mg/m3 PEL for grain dust (in those instances where oats, wheat, or barley are being handled) can be achieved by the use of full-facepiece respirators equipped with high-efficiency particulate (HEPA) filters. The use of such respiratory equipment, which affords a protection factor of 50[6], will provide sufficient protection where 8-hour TWA exposures to grain dust or to total dust do not exceed 500 mg/m3 or 750 mg/m3, respectively. In those rare instances where exposures exceed these values, it is believed that the observance of some simple work practices, such as lowering the loading chute to reduce the drop distance or having the operator stand away from the truck during the initial loading period, will reduce operator exposures to within a factor of 50 of the respective total dust and grain dust PELs.

¹² Out of 74 observations, 2,346 was the highest recorded exposure, 813.1 and 176.1 were the next highest exposures.

presented in Table V-D11. As shown, annual compliance costs are estimated to total \$2.7 million. These costs represent an estimate of compliance costs for large operations affected by the PEL extension. Operations (identified in chapter III) which have the potential for worker overexposure and will incur costs include:

· Silo operations:

Cotton ginning;
Post-harvest grain handling

operations; and
• Grape harvesting

This chapter summarizes for each process: (1) The extent of current worker exposure and the current baseline level of controls, (2) the additional controls

that will be needed to reduce worker overexposures, and (3) the costs that facilities in the agricultural sector will incur to achieve compliance with the PELs for the airborne contaminants of concern.

TABLE V-D11.—ANNUALIZED COSTS OF COMPLIANCE

Operation	SIC	Cost per facility	No. of facilities	Annual cost
Silo operations	0212, 024, 0214,			
Cotton ginning	0219	\$270	964	\$260,280
cost-harvest grain handling		3,334	581	1,937,054
	0721, 0722,			S S Alter
Grape harvesting	0723 0172	155 267	576 1,495	88,992 399,300
Total			3,616	2,685,626

Numbers may not compute due to rounding.

Costs-Silo Operations (SICs 0212, 024, 0214, 0219). The exposure data described by May[1] indicate that the dust exposures of employees involved in silo unloading exceed the 5 mg/m3 PEL for respirable dust in two of five (or 40 percent) of the facilities having silos. In Chapter III, it is estimated that silo unloading operations are conducted at approximately 2,400 agricultural facilities that employ more than 10 workers. Therefore, employee overexposures to dust during silo unloading currently occur in an estimated 964 (2,410×0.4) agricultural facilities. It is believed that, at most, two employees per facility are engaged in silo unloading operations on any given day during the approximately 90workday winter feeding season.

Current Baseline Controls. Meridian derived its data for baseline controls from observations made during site visits and discussions with representatives of agricultural extension services and the University of Iowa Institute of Agricultural Medicine and Occupational Health. Currently, no controls are used to reduce exposure to respirable dust in this process.

Estimated Costs of Controls.

Assuming that each such facility will purchase 180 disposable respirators [2 employees×90 workdays], at a unit cost of \$1.59[2], the estimated annual cost per facility to achieve the respirable and total dust PELs for silo unloading operations is \$270. Meridian estimates that the total annual cost for all affected facilities will be \$280,280 (\$270 per facility×964 facilities).

Cotton Ginning (0724). Based on NIOSH's survey of 35-gin operations[3], 86 percent of all gins are already achieving mean employee cotton dust exposures at or below the 500 µg/m³ level most of the time. However, Meridian estimated (Chapter III of its final report) that 10 percent of the ginning workforce, or 1,278 employees, continue to be exposed above the PEL. The exposures of most of these workers are within a factor of 2 of the PEL; in a few rare cases overexposures may exceed the PEL by a factor of 6.

Current Baseline Controls. An industrial hygiene/medical evaluation conducted by NIOSH from October 1980 through February 1981 dealt with three cotton gins on the Colorado River Reservation in Arizona[3]. The three gins studied in this investigation had moderately effective to no engineering controls for reducing airborne concentrations of cotton dust. One gin was processing first- and second-picked cotton at the time of the evaluation and had some local exhaust ventilation equipment to help control dust. Another gin was processing only first-picked cotton and had no exhaust ventilation equipment. The third gin was processing rood or last-picked cotton and also had no exhaust ventilation equipment.

Reduction of worker exposure to dust that results from the processing of cotton is being achieved in some facilities by the use of engineering controls[4]. These include the isolation of open processes and specific dust generation points with shutters to prevent contamination of other areas; use of conveyers and material transfer points; location of exhaust systems and air cleaner discharge points downwind and at a distance from building air inlets; and hooding.

Work practices are also used to reduce cotton dust levels. Examples of such practices include routine maintenance of local exhaust hoods, ductwork, dust collection equipment, and fans so that such equipment works at maximum efficiency and effectiveness; good housekeeping activities that are performed systematically and on a regular basis (e.g., vacuum cleaning rather than dry sweeping); and common-sense procedures, such as regular laundering of work clothes and keeping cotton away from the face.

Respiratory protection is also used during dusty activities (e.g. the use of compressed air cleaning in "blow down" operations). During NIOSH's multi-plant survey, personal protective equipment in evidence were hard hats and disposable paper respirators, which were (not NIOSH-approved) worn by about 10 percent of the employees in the survey.

Estimated Costs of Compliance. The exposure data presented in Chapter III from the Zey report[4] suggest that 50 percent of the estimated 1,162 cotton gins in the United States (or 581 facilities) must implement additional exposure control procedures to achieve the 500 μ g/m³ PEL for cotton dust. As described in Chapter V, it is believed that the 500 μ g/m³ PEL can be achieved in these facilities by improving housekeeping practices, and in

particular, by cleaning the ginning work area and equipment at the end of each shift. In facilities currently performing end-of-shift cleanup, all employees spend 30 minutes performing this activity before going off-shift[4]. Meridian believes that effective cleanup will require the use of HEPA-filtered vacuums rather than the dry sweeping or use of compressed air that is likely to be the method of choice in these plants at present. This recommendation is consistent with NIOSH's recommendation[4]

According to NIOSH[4], cotton gins employ 10 to 18 workers (or an average of 14 workers), and these workers work on two 12-hour shifts. It is therefore assumed that, on average, seven employees will be available per shift to perform cleanup activities. Assuming that a typical cotton gin operates 7 days per week over an 8-week season[4], it is estimated that a total of 392 hours per facility per year will be required to perform post-shift cleanup activities (7 employees/shift×0.5 hour/shift×2 shifts/day×56 days). At an average labor cost of \$8/hour[5], the estimated annual per-facility labor cost for end-ofshift cleanup is \$2,352.

In addition, it is assumed that each of the 581 cotton gins estimated to need this kind of routine cleanup will purchase three HEPA-filtered vacuums at an estimated capital cost of \$2,700[2] to use for post-shift cleanup. Assuming a useful life of 5 years, a 10-percent interest rate, and an annual maintenance cost of 10 percent of capital cost, an annualized cost for HEPA-filtered vacuum equipment is estimated to be \$982 for each affected facility. Thus, the total annualized cost. including labor costs for cleanup, estimated to be incurred by each affected facility to achieve compliance with the 500 μg/m³ cotton dust PEL is \$3,334 (\$982+\$2,352). The total annualized cost of compliance for this sector as a whole is estimated to be \$1,937,054 (\$3,334×581 facilities).

Post-Harvest Grain Handling Operations (SICs 011, 0721, 0722, 0723)

Current Baseline Controls. Employee exposures to grain dust during postharvest grain handling occur when grain is transferred from storage bins to trucks[6]. The exposure data presented in Chapter III show that these exposures range from 15.3 to 2,346 mg/m3 Currently, it is believed that no baseline controls are used to reduce employee exposures to OSHA's 10 mg/m3 PEL for grain dust.

Estimated Costs of Compliance. In Meridian's final report, it is estimated that 864 employees on 576 grain farms

employing more than 10 workers are overexposed to either grain dust (i.e., oats, wheat, or barley) or total dust as a result of unloading grain from storage bins (see Chapter III). The unloading of storage bins does not occur year-round; instead, bins are unloaded when the demand and price of grain are sufficiently high to warrant the shipment of grain to market. Consequently, the number of days on which workers are exposed to dust during this operation varies from facility to facility and from year to year. For costing purposes, it is assumed that employees are overexposed an average of 30 days per year and that every employee will be provided with a NIOSH/MSHAapproved full-facepiece respirator at an estimated cost of \$165 apiece[2]. Assuming a 5-year life expectancy for these masks and a 10-percent interest rate, the annualized cost for each respirator is estimated to be \$43. In addition, every employee will have to be furnished with a new pair of HEPA filters, at a cost of \$8.00 per pair[2]. every 4 days that unloading is performed. Assuming that employees perform this task on 30 days per year, the annual cost for HEPA filters is estimated to be \$60 per employee ([30 days/4]×\$8.00 pair). The total annualized per-employee cost of compliance is therefore estimated to be \$103 (\$43 and \$60). The industry wide annualized cost to provide this equipment to all 864 employees believed to be overexposed during grain unloading operations is estimated to be \$88,962.

Grape Harvesting (SIC 0172)

Estimated Exposure. For the grape industry sector, data presented in Chapter III suggest that 8,873 workers are potentially exposed to respirable silica and total dust during the manual harvesting of grapes. Of these, 5,324 workers are estimated to be overexposed at present to both respirable silica and total dust. In addition, 6,655 employees are estimated to be overexposed above the 15 mg/m3 PEL for total dust alone; this yields a maximum total of 6,655 overexposed workers in this sector (see Table V-D9).

Current Baseline Controls. Meridian found no controls being used to control exposure to respirable silica and total dust during the manual harvesting of

grapes.

Estimated Costs of Compliance. Based upon available exposure data[7], no grape harvest worker is currently exposed to a concentration of respirable silica or of total dust that is greater than five times the respective PEL; therefore, employers will be able to achieve

compliance both with the respirable silica and total dust PELs by ensuring that their employees wear disposable respirators, which have a protection factor of five[8]. Disposable respirators that are NIOSH/MSHA-approved for use against silica and total dust are available at a cost of \$1.50 apiece[2-p.

The grape harvest occurs in September and early October[7] and therefore, it is estimated that grape harvesters will need respirators over a period of about 40 work-days. The resulting cost per worker is estimated to be about \$60 per year (40 days × \$1.50/ day). OSHA estimates that the total annualized costs that employers will incur to comply with the PELs for respirable silica and total dust in grape and harvesting operations is \$399,300 (\$60 per year per worker × 6,655 workers exposed to silica and/or total dust).

Summary. Table V-D11 presents the estimated average cost of compliance per farm. Annual costs range from \$155 for post harvest grain handling, up to \$3,334 for cotton ginning operations. Total annual costs approach two million dollars for cotton ginning. The total annual cost for all affected farm operations is \$2.7 million.

6. Economic Impact, Regulatory Plexibility Analysis, and Environmental Impact Assessment

Introduction. This chapter investigates the potential economic impact on affected establishments as a result of the proposed standard. OSHA analyzed two alternative scenarios of the potential impacts of the proposed rulemaking. In the first, a total cost absorption or no cost passthrough scenario was assumed (all costs are borne entirely by affected establishments). In the second scenario,

total cost passthrough was assumed (all compliance costs are passed on in the form of price increases). In this scenario, estimates of the maximum inflationary impact were calculated. These impacts were estimated using compliance costs developed in Chapter VI.

Economic Impact. In the first scenario, perfectly elastic demand or zero cost-passthrough was assumed. The estimated economic impact of the rule for firms potentially affected is summarized in Table V-D12. These estimates represent the maximum industry impact within a market

scenario where none of the costs can be passed on to consumers and where there is no productivity offset to costs.

Table V-D12 shows that costs as a percentage of profits average .33%, with the highest impact in cotton ginning where costs as a percentage of profits is 1.4%. These results, however, represent a worst case, with the magnitude of the standard on profitability somewhat exaggerated because full absorption of the costs are not likely to occur. It should be noted that costs of this magnitude cannot affect the viability of even the smallest gins in this segment.

TABLE V-D12.-ECONOMIC EFFECTS: NO COST PASSTHROUGH SCENARIO

SIC	Industry	Annual cost per establishment	Average profit per 1 establishment	Costs as a percent of profit

7724	Crop Preparation Services for Market Except Cotton Ginning	155	2,555,783	0.0
J1 24	Cotton Ginning	3,334	1,779,383	0.1

Dun and Bradstreet, Dun's Insight Database.

In the second scenario, total cost pass-through was assumed. As demonstrated by the estimates summarized in Table V-D13, the impacts on market prices will not be significant. No price increase would exceed the .19% percent experienced by SIC 0724, cotton ginning. Price changes of this magnitude are not likely to result in market disruption or present an economic burden to consumers.

Based upon the data presented in Tables V-D12 and V-D13, OSHÅ has determined that the impact on the affected establishments is not significant to impair their economic viability and OSHA has made a preliminary determination that the proposed standard is economically feasible.

Regulatory Flexibility Analysis. In accordance with the Regulatory Flexibility Act (Pub. L. 96–353, 94 Stat.

1164 [5 U.S.C 601 et. seq.]], OSHA has assessed the impact of the rulemaking on small establishments. OSHA has determined that there will be no adverse economic impact on small agricultural establishments as a result of this rulemaking. This rulemaking is limited to agricultural establishments with 11 or more hired workers because of Congress's rider on OSHA appropriations which prohibits OSHA from using funds to proscribe, enforce or enact any standard that will affect farms with fewer than 11 employees. In Chapter II, it was determined that only 3.6 percent of all farm establishments have more than 10 employees; however, they produce more than 40% of all agricultural goods. Therefore, the proposed standard would only affect larger farms in the agricultural community. Small farms, which make up the remaining 96.4 percent of U.S. farms,

may be indirectly affected by becoming more aware of the chemical hazards in agriculture, but because these farms employ fewer than 11 persons they will not be directly affected by this rulemaking. Hence, OSHA has assessed the possible impact on small farms and determined that no small farm will be adversely affected.

Environmental Impact Assessment. This assessment has been prepared in accordance with provisions of the National Environmental Policy Act (NEPA) (42 U.S.C. 4325 et seq.) as well as the regulations on the Council on Environmental Quality (40 CFR part 1500), and DOL-NEPA Compliance Procedures (29 CFR part 11).

OSHA has reviewed the standard and the information submitted by its contractor. As a result, OSHA has concluded that no significant adverse

environmental impacts are likely to occur as a result of this proposed standard. In fact, it is possible, that as a result of this rulemaking, persons using hazardous chemicals will be more aware of the possible consequences of exposure to these chemical. This could result in better controls and practices during the application of these substances. This in turn could have a beneficial environmental impact and OSHA invites public comment on this

potential benefit.

International Trade Impact. Currently, some European countries have PELs which cover all aspects of the private sector, including agriculture. The United Kingdom has over 200 such PELs, one of which is a PEL of 10 mg/m3 for grain dust. The Federal Republic of Germany has a cotton dust PEL of 1.5 mg/m3. In addition, a committee empowered by the European Economic Community (EEC) is compiling list of PELs which members may someday be required to follow. Although their work is in its preliminary stages, once the list is completed it could be used as a market barrier by the EEC against U.S. agricultural products which were not produced by workers afforded protection from airborne contaminants. Currently, there is no trade barrier as such, however, one could develop if the United States does not afford its agricultural workers protection from air contaminants.

Summary. Based on the data summarized in Tables V-D12 and D-V13, OSHA has concluded that the economic impacts of the standard are clearly feasible for the agricultural sector and that the proposed rule is not expected to have an adverse affect on small establishments and the environment.

E. Preliminary Regulatory Impact Analysis for General Industry

1. Introduction

The Occupational Safety and Health Administration (OSHA) currently does not have specific permissible exposure limits (PELs) for mineral wool, fibrous glass, and asphalt fume. These substances are covered under the PEL for particulates not otherwise regulated (PNORs), which limits employee exposures to 15 mg/m3 total dust and 5 mg/m³ respirable dust. OSHA proposes to establish new PELs for these substances to protect the health of workers.

This section examines the potential effects associated with this proposed rulemaking. The nature and extent of occupational exposures are identified and the affected industries are profiled. The technological feasibility, the estimated costs and benefits, and the economic impacts of compliance with the proposed rule are presented.

2. Industry Profiles

Mineral wool and fibrous glass. An important consideration in discussing industries involved in the production and use of vitreous fibers is the use of appropriate definitions. For purposes of this analysis, the term man-made vitreous fiber (MMVF) is used as a generic term for a variety of fibers, including fibers made of rock, slag, minerals and glass. This analysis will consider mineral wool as a subset of MMVF, consisting of slag and rock wool. Fibrous glass is considered a separate subset of MMVF, distinct from mineral wool. OSHA intends that the proposed PEL for fibrous glass also applies to refractory ceramic fiber (RCF), and the exposures and potential impacts are analyzed for this substance as well. This preliminary analysis is based on research conducted by CONSAD Research Corporation [1], and on data supplied by the industry trade

association, TIMA [2].
Standard industrial classification (SIC) codes 3296, 3297, and 3299 include over 70 establishments producing mineral wool, fibrous glass, RCF, and related products such as insulation and acoustical tile. In 1988, the latest year for which data are available, these plants employed over 28,000 workers and shipped over \$3.2 billion worth of fiber products. Most of the shipments were fibrous glass products, including ordinary glass wool, insulation material. and continuous filament. Approximately 15 percent of the shipments were mineral wool products. The remainder was made up of special fine fiber and

other vitreous fibers.

Mineral wool, fibrous glass, and RCF are available in a variety of different forms, reflecting a range of applications for these products. Blankets, batts, modules, textiles, boards, and vacuumformed plastics are primarily fabricated in the bulk material manufacturing plants and can be made to customer specifications. Some bulk material is also sold to independent fabricators for making refractories.

Fiber-containing products are commonly used for insulation and fire protection applications. Fibrous glass is more prevalent in residential applications, and RCF tends to be used more in industrial and commercial applications. In addition to structural insulation, these products provide effective insulation for heating and cooling equipment, furnaces, tanks and storage facilities, pipes and ducts, and

components of automobiles, ships, and airplanes. Fibrous products can also be used in reinforced plastics with applications in aerospace, appliances. construction, consumer goods, electrical equipment, protective gear, farming, and other areas.

Table V-E1 provides a summary of the industries associated with mineral wool, fibrous glass, and RCF products that involve employee exposures to airborne fibers. Most of the occupational exposure of concern in general industry occurs in the fiber manufacturing plants. which includes much of the fabrication of fiber-containing products. The potential for employee exposures may also exist for independent fabricators in the production of refractories and reinforced plastics where loose bulk fiber is used in the manufacturing process. The installation and removal of furnace linings and other insulation may involve employee exposures if fibers become airborne. The use of products made from or containing fibrous glass, RCF, or mineral wool generally does not result in significant occupational exposures during secondary manufacturing applications. For example, exposure to airborne fibers during the installation of preformed insulation in appliances or catalytic converters would be minimal.

Asphalt fumes. Asphalt is a constituent of most crude petroleum and is produced as part of the petroleum refining process. The total number of companies in the petroleum refining industry (SIC 2911) with the capacity to produce asphalt as a main product or byproduct in 1989 was estimated to be 72 [1]. According to statistics published by the U.S. Department of Commerce. the 309 establishments in SIC 2911 employed more than 50,000 production workers, and their total value of shipments in 1987 was \$118.2 billion of which asphalt manufacturing

represented a minor fraction [3]. Asphalt is used in the manufacture of a wide variety of products. The two main categories of products are paving mixtures (SIC 2951) and roofing products (SIC 2952). Asphalt may also be an ingredient for some paints and varnishes, but this minor application has not been found to be associated with any significant exposures [1].

Asphalt paving mixtures are produced at an estimated 4,000 establishments with total estimated sales of over \$4.3 billion. Many different mixtures are available depending on the application and the specific properties desired. Asphalt paving mixtures are primarily used to pave streets, highways, and airfields.

Approximately 102 establishments produce an estimated \$3.4 billion worth of roofing products annually. The products include asphalt saturated sheathing, boards, felts, and fabrics, asphalt roof cements and coatings, and asphalt shingles. Most of these products are used by roofing contractors, which are part of the construction industry.

Table V-E2 provides a summary of industries involved in the production of asphalt and asphalt products.

3. Employee Exposures and Benefits

Mineral wool, fibrous glass, and RCF. Data on occupational exposures to these fibers are available from several NIOSH studies, from OSHA inspection experience, and from industry sources. Estimates of the numbers of exposed employees are based on figures reported by CONSAD and are derived from Department of Commerce data and industry sources [1].

An estimated 3,400 workers are potentially exposed to mineral wool (rock or slag wool) fibers in general industry. About 2,110 of these workers are involved in the production of mineral wool and mineral wool insulation materials. The use of mineral wool in the production of acoustical tile involves potential exposures to about 1,290 workers.

A NIOSH study of five mineral wool producers showed that worker exposures to respirable dusts and fibers were relatively low. Personal breathing zone sample results taken of production workers indicated that all exposures were below 1 f/cc. Mean fiber concentrations were reported to be 0.125 f/cc across all job categories, with the highest exposures occurring for laboratory and quality control workers at 0.196 f/cc. The mean of the total airborne particulate material concentrations for all facilities was 0.621 mg/m³.

NIOSH also surveyed workers in two plants that used mineral wool in their products. One of the manufacturers produced industrial insulation and the other produced ceiling tiles. In the industrial insulation plant the mean fiber concentration for all exposed production workers was 0.208 f/cc as an 8-hour time-weighted average (TWA8). In the tile plant, occupational exposures ranged from 0.72 f/cc to 3.12 f/cc; these averages correspond to activities for which the sampling time may have been less than two hours. The highest exposures occurred during the mixing of raw materials.

These data are considered to represent upper bounds of current

occupational exposures for two reasons. First, the NIOSH survey of the manufacturing facilities was done in 1980 and significant improvements in controls have been implemented since then. Second, the data reflect samples taken during activities that were considered to have the highest potential exposures and that may occur intermittently. The eight-hour timeweighted average (TWA8) exposures would be considerably lower.

More recent exposure data was collected by TIMA, the industry trade association. TIMA submitted a report to NIOSH in 1990 which included up-todate industrial hygiene data of occupational exposures to vitreous fibers in five mineral wool manufacturing plants [2]. One of the plants also produced acoustical tile from mineral wool. The data were collected over a 17 month period from 1988 to 1989. None of the job categories had mean exposures above 0.6 f/cc TWA8. Area samples in tile manufacturing operations ranged from 0.31 f/cc to 0.64 f/cc.

Exposure monitoring data submitted by three different companies and covering 17 plants manufacturing mineral wool and/or acoustical tile show that most exposures are below 0.4 f/cc. Only two plants reported fiber concentrations above 0.5 f/cc.

In plants where employees are exposed to airborne mineral wool fibers. the use of personal protective equipment is widespread. Disposable respirators are the most common form of protection from the inhalation of fibers; in addition, some employees use face shields, earmuffs, and protective clothing.

Data on occupational exposures to fibrous glass and special purpose glassy fibers have been documented by NIOSH studies, collected from OSHA compliance inspections, and reported by TIMA in their July 10, 1990 document submitted to NIOSH.

An estimated 26,220 workers are potentially exposed to fibrous glass or RCF in primary manufacturing facilities The majority of these workers (16,758) are involved in the production of ordinary fibrous glass wool and insulation material. Another 8,437 workers are estimated to be exposed during the production of continuous filament fibrous glass, and about 1,025 workers produce special fine fibers and other vitreous fiber products such as RCF.

The TIMA report summarizes a comprehensive database consisting of 1,570 samples of occupational exposure measurements taken between 1985 and 1989 in various types of manufacturing

facilities producing and using fibrous glass.

The mean occupational exposure during the production of glass wool was 0.11 f/cc. The production of continuous filament for use in fiberglass textiles resulted in mean occupational exposures of 0.03 f/cc. Samples taken during the production and use of very fine diameter glass fiber for special filtration products averaged 1.42 f/cc with over 77 percent of the samples falling below 1 f/cc. Occupational exposures during the production of RCF, a ceramic fiber, averaged 0.65 f/cc, and almost 80 percent of the samples collected were below 1 f/cc. As in mineral wool production, respiratory protection and other personal protective equipment is widely used in the production of fibrous glass and RCF.

Workers may be also exposed to fibers during a variety of secondary manufacturing applications. The TIMA database contains over 440 exposure samples taken in a variety of fibrous glass user industries. The mean fiber concentration found in the end use applications was 0.25 f/cc.

In general industry, the primary end use applications of concern include the installation and removal of insulation products with industrial applications, and the addition of fiber products in the production of refractories and plastics by independent fabricators. Based on the available data and on knowledge about the nature of the activities and materials involved, CONSAD concluded that uses of fibrous glass products in other secondary manufacturing applications in general industry would very rarely involve significant airborne fiber exposure.

The available NIOSH and OSHA data on occupational exposures to fibrous glass are primarily concentrated in the user industries. NIOSH conducted a study of a shingle manufacturing plant which produces shingles with fibrous glass cores. The results from the personal samples were reported by the laboratory as not detectable. The lower limit of detection was determined to be 0.01 f/cc. In a review of OSHA sampling results, the only job category in general industry found with mean exposures above 1f/cc was the saw operator in refractories production.

An estimated 200 employees are potentially exposed to fibers during the production of refractories and plastics in 20 facilities other than the primary manufacturing plants. Exposures for these workers average about 0.7 f/cc TWA8; the highest average exposure, 1.8 f/cc, was recorded for the saw operator [1].

The installation and removal of insulation in industrial applications is performed by maintenance employees and by independent contractors. Substantial insulation work for furnaces, pipes, process equipment, and fire protection occurs at about 1,800 facilities annually. In addition to over 10,000 employees at the facilities involved in this work regularly, jobs are also handled by about 70 independent contractors. A total of about 11,000 employees are engaged in this type of work, which generally entails potential exposure to RCF.

Exposure levels can vary significantly depending on the specific circumstances of a job and the type of product used. Health and safe handling information and outreach programs have been developed by RCF producers to assist users in adequately protecting employees. Monitoring results indicate that exposures are usually less than 1f/cc. Respirators are recommended when fiber levels are unknown.

Table V-E3 summarizes occupational exposure to fibrous glass, RCF, and mineral wool fibers in general industry. For each industry, the number of exposed employees and their typical exposure levels are presented. Exposure levels reflect ambient air concentrations in the employees' breathing zones and do not take the use of respiratory protection into account. Potential overexposures are most likely to occur during the production of acoustical tile, special fine fibers, and RCF; in the fabrication of refractories; and in the installation and removal of insulation.

The number of employees exposed above the proposed PELs is derived by estimating the probability of an overexposure among the workforce in each industry sector. Even in industries with mean exposures less than 1 f/cc the exposure data indicate that some employees may occasionally be exposed at levels greater than 1 f/cc or at levels exceeding the mixed exposure limit. Although detailed data on the specific distributions of exposures by job category are not available, the number of employees exposed above the proposed PELs can be estimated from information on the frequency distribution of sampling results.

TABLE V-E3.—SUMMARY OF OCCUPA-TIONAL EXPOSURES TO MINERAL WOOL, FIBROUS GLASS, AND RCF IN GENERAL INDUSTRY

Industry	Number of exposed workers	Mean expo- sure levels (f/cc)
Mineral wool production:		
Wool and insulation	2,110	2 0.4
Acoustical tile	1,290	.5
Fibrous glass production:	-	
Wool and insulation	16,758	2.2
Continuous filament	8,437	2.2
Special fine fiber	425	1.4
Other, including RCF	600	.7
fractories	200	7
Insulation work	11,000	.6

¹ Products made from or containing fibers are used throughout industry in many applications with minimal potential for exposure to airborne fibers. ² Less than.

Source: Office of Regulatory Analysis, OSHA; based on CONSAD Research, 1991 [1].

OSHA estimates that compliance with the proposed PEL of 1 f/cc would result in lower exposures for about 2,000 employees working with fibers in general industry. This number represents about 1,500 workers in insulation work and about 100 workers each in the production of acoustical tile, special fine fiber, RCF, refractories, and plastics that would be overexposed at some time during the year without adequate respiratory protection. The full-time equivalent number would be 1,400 workers, including 1,000 insulation workers.

The benefits of establishing a lower PEL for mineral wool and fibrous glass include a reduction in cases of respiratory disease. Several epidemiological studies have shown significant excess mortality from such disease for workers that have been exposed to these fibers. More detailed information on the specific health effects associated with exposure to mineral wool and fibrous glass can be found in the health effects section of this preamble.

The epidemiological studies demonstrating significant excess mortality among cohorts with exposure to fibers typically show increases in incidence rates of 30 percent or more. The elevated incidence rates usually correspond to relatively high exposure levels, but the available evidence indicates that workers face a significant risk of disease at exposure levels above 1 f/cc. On average, the rate of occupationally induced respiratory disease should decline among the affected workers. If it is assumed that

the excess risk over a working lifetime would be reduced to less than one in one thousand, from two to four cases could be expected to be prevented over 45 years among the workers exposed

above the proposed PEL.

Several studies link exposure to these fibers with illnesses such as chronic rhinitis, chronic coughs, bronchitis, fibrosis, and other conditions. A recent health hazard evaluation conducted by NIOSH at a fibrous glass manufacturer (RDHETA 90-145-2086, November, 1990) found that fifty to sixty percent of the workers participating complained of chronic cough, shortness of breath, and irritation of the eyes, skin, and upper respiratory tract (some of these symptoms may have been associated with smoking). Based on exposure monitoring data collected by NIOSH. exposure levels at the plant are representative of those in the industry.

Reductions in exposures as a result of achieving compliance with the proposed rule are estimated to prevent about 500 illnesses each year associated with exposures to fibers. Most of these illnesses are not expected to involve lost workdays; the annual number of lost workday illnesses potentially prevented by the proposed rule is estimated to be about 100. OSHA requests comments on the prevalence of health effects among workers exposed to fibrous glass and mineral wool, and on the effectiveness of compliance with the proposed rule in preventing such effects.

Based on research by Kip Viscusi, the implicit average value of avoiding each lost workday case would be about \$40,000. This value is based on a willingness-to-pay methodology and takes existing compensation programs into account. The total potential benefit associated with the prevention of lost workday illnesses due to exposures to fibrous glass and mineral wool in general industry would be \$4 million.

Asphalt fumes. Workers with occupational exposure to asphalt fume can be found in three industry categories within general industry. Approximately 144 workers may be exposed to asphalt fume during asphalt production; the production of paving mixtures involves approximately 12,000 production workers; and the manufacture of roofing products involves an estimated 7,100 production workers.

The production of asphalt in petroleum refineries is a highly automated process. In a typical plant, only two workers are required to operate the equipment. The production system is sealed and thus emissions of asphalt fume are minimal. Personal breathing zone samples were taken of

workers during a site visit to an asphalt manufacturing refinery by CONSAD. The analysis of the samples revealed that the workers were exposed to the benzene soluble fraction of asphalt fumes at levels below 0.08 mg/m³.

Asphalt paving mixture manufacturing facilities are also generally automated, limiting the potential for employee exposures. OSHA inspection data for these facilities indicate that exposures range from 0.197 mg/m³ to 0.350 mg/m³. The National Asphalt Paving Association found that the mean exposure to the benzene soluble fraction of asphalt fume in two asphalt cement manufacturing plants was 0.297 mg/m³.

During the production of roofing products, employee exposures to asphalt fumes may be slightly higher. OSHA inspection data collected in five different plants manufacturing asphalt felts and coatings revealed exposures to the benzene soluble fraction of asphalt fume as high as 0.887 mg/m³. Exposures for most employees were below 0.4 mg/m³. Occupational exposures in plants manufacturing other roofing products, including shingles, are expected to be similar.

Table V-E4 summarizes the data on occupational exposures to asphalt fumes in general industry. The estimated number of exposed employees and the corresponding mean exposure levels are presented for each industry category. OSHA preliminarily concludes that employees involved in the production of asphalt, paving mixtures and roofing products are generally exposed below the proposed PEL of 5 mg/m3. However, most employees involved in the production of paving mixtures and roofing products may be potentially exposed above an alternative PEL of 0.2 mg/m³.

The potential benefits associated with compliance with the proposed standard of 5 mg/m³ or the alternative standard of 0.2 mg/m³ can be calculated by applying a quantitative risk assessment (QRA) developed for asphalt fume, which is discussed in detail in another section of this preamble. The QRA establishes a linear (proportional) relationship between lifetime cumulative exposure and risk of lung cancer, without threshold effects.

TABLE V-E4.—SUMMARY OF OCCUPA-TIONAL EXPOSURES TO ASPHALT FUMES IN GENERAL INDUSTRY

Exposure industry	Number of exposed workers	Mean levels (mg/m³)
Asphalt production	144	10.1
Asphalt paving mixtures	12,000	.3
Roofing products	7,100	.5

1 Less than.

Source: Office of Regulatory Analysis, OSHA; based on CONSAD Research, 1991 [1].

In order to derive the potential benefit of the alternative PEL of 0.2 mg/m3, the QRA is applied to exposures that would be lowered to comply with the standard. OSHA estimates that 12,000 full-time equivalent workers are exposed at an average of 0.3 mg/m3 in the production of paving mixtures, and that 7,100 workers are exposed at an average of 0.5 mg/m3 in the production of roofing products. If the QRA for asphalt fume is used to predict the excess cancer risk among these workers, the number of lung cancer cases expected to be attributable to these exposures over 45 years would be 36.

The exposures are likely to be reduced through the use of half-mask respirators with organic vapor cartridges and other controls which have an estimated protection factor of at least ten. Assuming full compliance with the standard would reduce average exposures to the benzene soluble fraction of asphalt for these workers to 0.05 mg/m³ over a working lifetime, the number of excess cancers expected to be prevented over 45 years would be 31.

With a PEL of 0.5 mg/m³, an estimated full-time equivalent of 2,000 workers producing paving mixtures and 3,000 workers producing roofing products would be exposed above the PEL. About 2,000 FTE workers in each industry would need respiratory protection. The number of excess cancers prevented over 45 years with full compliance would probably be fewer than 10.

With the proposed PEL of 5 mg/m³, it is unlikely that routine exposures would need to be reduced for any employees. Corresponding benefits would probably be close to zero.

4. Nonregulatory Alternatives

The new PELs for asphalt fume, mineral wool, and fibrous glass are proposed for general industry in conjunction with the accompanying proposed rulemaking for the construction industry.

The proposed construction industry regulation would add or revise PELs for over 400 substances, including asphalt fume, mineral wool, and fibrous glass. OSHA has determined that the proposed rule for the construction industry is necessary to ensure adequate protection of the health of construction workers. The analysis of nonregulatory and other alternative approaches for achieving this goal is included in the preamble of the proposed rule for construction.

New PELs are being proposed in the construction industry for asphalt fume, mineral wool, and fibrous glass; this proposed rule for general industry would ensure that the PELs are consistent for all workers. The alternative to this approach would be to establish different PELs for employees depending upon the industrial classification of the employer. OSHA has rejected this approach and has adopted a regulatory approach which recognizes the inherent hazardous nature of the substances being regulated and the desirability of affording equal protection to all workers exposed to the substances.

E. Technological Feasibility

OSHA has preliminarily determined that compliance with the proposed PELs for asphalt fume, fibrous glass, and mineral wool can be achieved with technology that is currently available and utilized in general industry. In operations where airborne concentrations cannot be reduced below the proposed PEL through the implementation of feasible controls, employees would be required to wear respirators. With a PEL of 0.2 mg/m3, OSHA anticipates that such situations may occur in most facilities involved in the production of asphalt paving mixtures or roofing products. Additional respirator use would probably not be necessary to comply with a PEL of 5 mg/ m3 in any of the affected industries.

Data on occupational exposure to asphalt fume indicate that current occupational exposures are generally below 0.2 mg/m³ during the production of asphalt. Employees control the highly automated process from air conditioned control booths with computerized

equipment.

Recent technological advances have made the production of asphalt paving mixtures a relatively automated process at most plants. The facility operator can generally make most of the adjustments during a normal working day without leaving the control room. The ticket dispatcher usually coordinates and monitors the flow of trucks and loads of materials and may work in the control room or in a separate building. A frontend loader operator loads the feed bins

with aggregates; such equipment can be outfitted with air conditioned cabs. Other employees work throughout the facility making necessary adjustments, performing preventative maintenance, and carrying out other responsibilities. Employees for whom airborne concentrations exceed the PEL could be adequately protected with an appropriate respirator.

Employees currently manufacturing asphalt roofing products may be exposed above a PEL of 0.2 mg/m3 for asphalt. Most of these facilities already utilize feasible controls to reduce employee exposures, such as local exhaust ventilation at emissions sources. Although some increase in the effectiveness of controls or the application of additional controls may be possible, OSHA expects that many employees would be required to wear respirators. At the airborne concentrations found in this industry. respirators would be capable of providing sufficient protection from asphalt exposure.

The available data indicate that the production and use of mineral wool and mineral wool insulation in general industry usually does not involve exposures above 1 f/cc. During the manufacture of acoustical tile with mineral wool, some occupational exposures above 1 f/cc have been recorded, but these may not occur in all plants. Monitoring results from seven plants manufacturing and using mineral wool products showed no employee exposures above 0.3f/cc [2].

Occupational exposures during the production of fibrous glass wool, insulation, and continuous filament are generally below 0.2f/cc. Less than 2 percent of the workforce exposed to fibrous glass is involved in the production of special fine diameter fibers. Monitoring results during this process have averaged 1.42 f/cc, and over 77 percent of the observed fiber concentrations for employees exposed in these operations were less than 1 f/cc.

CONSAD Research has analyzed the circumstances of exposure in the production of fine diameter fibers and has concluded that the installation of additional engineering controls at work stations with exposures above 1 f/cc would enable exposures to be controlled below the proposed PEL [1]. The engineering controls could include improved general and local exhaust ventilation systems, portable vacuum systems, and enclosures. Improved work practices may also be able to reduce exposures in some cases. Respirators may be used to achieve compliance with

the PEL if additional engineering controls are infeasible.

The available data on the production of RCF and the use of vitreous fibers in secondary manufacturing applications indicate that exposures are generally below 1 f/cc. In some exceptional circumstances exposures may be higher; the application of standard engineering controls alone or in combination with some supplemental respirator use would ensure compliance with the proposed PEL.

6. Costs of Compliance

Achieving full compliance with the proposed exposure levels for asphalt fumes, mineral wool, and fibrous glass would require additional expenditures on controls by some firms in general industry. Facilities with airborne concentrations above the proposed PELs would incur costs to reduce those levels.

The estimation of costs associated with the controls necessary to reduce exposures is consistent with the hierarchy of controls specified by OSHA. Respirators are to be used as a last resort if feasible engineering controls and work practices are insufficient.

The exposure profile and the feasibility of additional controls was evaluated by CONSAD Research Corporation under contract with OSHA. CONSAD identified the work stations and industries where additional controls would be needed, determined the effectiveness of the controls, and estimated the unit costs associated with the controls. The annualized incremental costs per plant and for each industry sector were calculated. OSHA supplemented the data in the CONSAD report with additional information submitted to NIOSH in response to the request for public comments on occupational asphalt exposure [F.R. Vol. 55, July 17, 1990].

Exposure monitoring data for employees involved in the production of asphalt indicate that the eight-hour time-weighted average exposures are sufficiently low to enable firms to be in compliance with the proposed PEL of 5 mg/m³ and with the alternative PEL of 0.2 mg/m³ without incurring costs for additional controls.

Mean exposure levels during the production of asphalt paving mixtures may exceed the alternative PEL of 0.2 mg/m³, and additional controls would need to be implemented to ensure compliance in these establishments. Front-end loader operators could be protected by an enclosed cab with a filtered air supply which is estimated to cost \$4,000. Assuming such a cab would

be necessary for an average of one loader at half of all affected asphalt pavement facilities, the resulting total estimated capital cost would be \$8 million. Based on an expected life span of 10 years and an annual cost of capital of 10 percent, the corresponding annualized cost would be \$1.30 million.

Additional engineering controls and improved work practices should be used to reduce exposures before relying on respiratory protection. Due to the current extent of automation and the mobile nature of the work at asphalt pavement facilities, the implementation of significant additional controls does not appear to be feasible. Employees outside of the control rooms for prolonged periods would probably have to wear half-mask respirators with organic vapor cartridges to comply with the alternative PEL of 0.2 mg/m3. An average of three employees per facility (a total of 12,000 employees) may be affected by this requirement on an average of two out of three work days. This would represent 8,000 FTE workers.

For purposes of estimating the cost of complying with the alternative PEL of 0.2 mg/m3, it is assumed that 12,000 respirators would be purchased for \$22 each. With an average life span of five years, the annualized cost would be about \$70,000. In addition, the respirator cartridges would need to be replaced on average for 8,000 workers every four days at a cost of \$8 per set. This would amount to an annual cost of \$4.16 million (260 work days per year divided by four, multiplied by \$8 and by 8,000 workers). Total annualized costs of compliance for this industry are estimated to be \$5.53 million.

With a PEL of 0.5 mg/m³, exposures for front end loaders may not need to be reduced, and the number of employees requiring respiratory protection is estimated to be a full-time equivalent of 2,000 workers. The purchase of 4,000 respirators would have an annualized cost of about \$23,000, the replacement of cartridges for the equivalent of 2,000 workers every four days would cost \$1.04 million, and the total annualized cost for this industry would be approximately \$1.06 million.

Compliance with the proposed PEL of 5 mg/m³ is not expected to result in additional costs for the production of paving mixtures or for the manufacture of roofing products.

Manufacturers of roofing products would be required to provide additional exposure controls for most employees to achieve compliance with the alternative PELs of 0.2 mg/m³ and 0.5 mg/m³. Plants in this industry already use local exhaust ventilation systems at emission sources to some extent. New or

improved 300 ventilation systems, other engineering controls, and changes in work practices would have to be implemented to the extent feasible in each plant to reduce exposures. Feasible controls generally include all practical and reasonable efforts to reduce exposures without resorting to building new plants or making drastic changes in the manufacturing process.

For purposes of estimating the costs of compliance that may be associated with the proposed standard, OSHA assumes that an average of \$100,000 per plant could be spent on additional engineering controls, including new or improved ventilation systems, clean air islands, and enclosures. This amount represents potential incremental changes that may produce substantial reductions in exposures. For example, a study conducted by PACE, Incorporated for several other industries demonstrates that significant improvements in control technology can be achieved with such expenditures (Attachment to Exhibit 19-43 in OSHA docket H-057a). Annual costs associated with power and maintenance of these systems and with other elements of an exposure control program are estimated to be about \$10,000 per plant. The estimated annualized cost of additional engineering controls for the industry would be \$2.68 million.

The costs for additional engineering controls primarily represent an allowance for the costs of complying with the requirement to implement controls "whenever feasible." OSHA expects that plants in this industry have already implemented most feasible engineering controls and that further reductions in exposures through the implementation of additional controls would be marginal. OSHA invites comments on this preliminary assessment.

Although the implementation of additional controls would reduce exposure levels, it is likely that supplemental respiratory protection would be necessary for some employees. The data compiled by CONSAD indicate that two of seven job categories (the coater and the head saturator) have the highest average exposures and that engineering controls alone may not be able to achieve levels below 0.2 mg/m³ or 0.5 mg/m³ consistently in these operations. OSHA estimates that respiratory protection

would have to be provided for about 2,030 employees on a full-time basis.

These employees would have to wear half-mask respirators with organic vapor cartridges. The respirators would cost about \$22 each and have an estimated

life span of five years; the annualized

cost for these would thus be \$11,781. The cartridges would need to be replaced once every four days on average for about \$8 per set, for an annual cost of \$1.06 million (260 work days per year, divided by 4, multiplied by \$8 and by 2,030 workers). The annual cost for the industry for respiratory protection would be about \$1.07 million. The total annualized cost of compliance for the manufacturers of roofing products with an alternative PEL of 0.2 mg/m³ would be an estimated \$3.75 million.

During the production of acoustical tile from mineral wool, additional controls would be necessary in some plants to ensure compliance with the proposed PEL. CONSAD estimated that 13 plants would need to install additional controls at 3 work stations. The controls would primarily consist of local exhaust ventilation and would have an estimated annualized unit cost of about \$3,000. In addition, three of these plants would need to supplement the engineering controls with respiratory protection for approximately 23 employees each. The total annualized costs of compliance for ceiling tile manufacturing would be about \$131,000.

Two of the plants involved in fibrous glass production produce specialty fine fibers. Occupational exposures during this process may exceed the proposed PEL. An estimated six work stations in each plant would be affected. The installation of improved ventilation systems is the recommended method of control, and it is believed that these controls would be sufficient to ensure compliance with the proposed PEL. Improved housekeeping and changes in work practices may also reduce exposure levels. The total annualized costs for the two plants are estimated to be \$18,660.

About 20 plants in secondary manufacturing applications may also need additional controls to meet the proposed PEL for fibrous glass. Plants most likely to be affected are associated with the production of refractories (including textiles and boards) and plastics. CONSAD estimated that each plant would have one affected work station that could be adequately controlled with standard ventilation systems. Annualized costs per plant are estimated to be about \$3,000 and the estimated total annualized cost of compliance for these plants is \$60,000.

The production of RCF involves potential exposures to airborne fibers. These plants have generally implemented feasible controls and respirator programs that adequately protect most workers from exposures above the proposed PELs. Additional

compliance costs as a result of this rulemaking would include providing respiratory protection for those employees intermittently exposed above 1 f/cc who currently do not wear respirators. Providing such protection for the equivalent of 60 full-time employees is estimated to cost \$23,000 annually. Some plants may be able to implement additional engineering controls or improved housekeeping programs to reduce exposures below 1 f/cc; such alternatives would probably have comparable costs on an annual basis.

Workers may be exposed to RCF during the installation or removal of insulation products. The manufacturers of these products provide extensive information about the safe use of the products, including recommended work practices, potential health effects, and literature and videos on providing

training and protecting the health of workers. Most employees involved in this type of work appear to be adequately protected with the appropriate combination of controls, work practices, and respirators. Additional costs for complying with the proposed PEL would be incurred for those employees who are exposed above 1 f/cc and not already protected. OSHA estimates that supplemental respiratory protection may be necessary for about 1,000 full-time equivalent employees at an annual cost of about \$375,000.

Tables V-E5, V-E6, and V-E7 summarize the estimated costs of compliance with this rule with a proposed PEL for asphalt of 5 mg/m³ and with alternative PELs for asphalt of 0.2 mg/m³ and 0.5 mg/m³, respectively. OSHA requests that any comments regarding these preliminary estimates,

including supporting or contradictory evidence, be submitted to the record to ensure that the potential regulatory impacts are accurately evaluated for the final rule.

The total annualized estimated cost of compliance for this rule with the proposed PEL for asphalt fume of 5 mg/m³ is \$0.6 million, all of which would be attributable to the new PELs for fibers.

The total annualized estimated cost of compliance for this rule with an alternative PEL for asphalt fume of 0.2 mg/m³ in general industry would be \$9.89 million. Most of these costs are attributable to compliance with the PEL for asphalt fume for which the primary exposure control measure would be the use of respirators. With an alternative PEL for asphalt fume of 0.5 mg/m³, the estimated total cost would be \$5.42 million.

7. Economic Impacts

The costs of compliance presented in the previous section were evaluated for their likely economic impacts in each of the affected industries. OSHA compared the estimated costs of compliance with data on annual revenues and profits for each sector.

The estimated costs necessary to achieve compliance with the proposed regulation are generally small in relation to revenues and profits. Table V-E8 shows the costs of compliance as a percentage of revenues and profits for each affected industry sector with an alternative PEL for asphalt fume of 0.2 mg/m³. The economic feasibility of a PEL for asphalt fume of 0.5 mg/m³ or 5 mg/m³ is established by demonstrating the economic feasibility of a PEL of 0.2 mg/m³.

The industry sectors affected by the proposed regulation would be the production of acoustical tile from mineral wool, the production of special application fine diameter glass fibers, the production of RCF, secondary manufacturing with vitreous fibers for refractories and plastics, insulation work in general industry, the production of asphalt pavement, and the manufacture of asphalt roofing products. The estimated compliance costs represent less than 0.15 percent of the revenues in each sector. The affected firms should be able to recoup the compliance costs with minimal price increases that would appear insignificant in comparison to other factors influencing production costs and

In the worst-case scenario where firms would not be able to bear any increase in prices without significant reductions in sales volumes, the estimated compliance costs would represent less than 4.5 percent of the pre-tax profits in each of the affected sectors. The resulting reductions in profitability would not be likely to cause significant impacts on the structure or viability of the affected sectors.

The compliance costs would probably be absorbed through some combination of slight price increases and reductions in profits. Most of the plants already have established safety and health programs to monitor the conditions of the work environment and control worker exposures to the extent necessary. This regulation would make it necessary for some plants to increase these efforts by targeting lower exposure levels corresponding to the proposed PELs.

In the mineral wool, fibrous glass, and RCF industries most employee exposures are already less than the proposed PEL of 1 f/cc; the compliance costs represent a marginal increase in the substantial efforts currently made to control exposures in these industries.

Compliance with the proposed PEL of 5 mg/m³ for asphalt would not require additional expenditures and thus is considered economically feasible.

Compliance with the alternative PEL of 0.2 mg/m³ for the benzene soluble portion of asphalt fume would probably require widespread use of respiratory protection in the asphalt pavement and roofing products industries. The estimated costs of controls reflect an approach of installing engineering controls to the extent feasible. Feasible controls would include reasonable,

practical measures and exclude excessively costly or extravagant measures. The total estimated costs of compliance would be economically feasible.

The overall demand for asphalt products should not be significantly affected. Substitutes, when available, are likely to be of poorer quality or more expensive. The usefulness of and need for asphalt products makes the demand relatively inelastic. Ultimately, the costs of the increased protection of the health of employees working with asphalt would result in slight increases in the costs of roofing and paving work.

Regulatory flexibility analysis. OSHA has preliminarily concluded that this proposed regulation would not have a significant adverse impact on a substantial number of small establishments.

The proposed rule is not expected to have a significant adverse impact on the affected establishments because the costs of compliance would be small in comparison to both revenues and profits. There are no indications that small establishments would be disproportionately burdened by the proposed requirements. The controls necessary to reduce employee exposures are not associated with significant economies of scale, and the need for additional controls is primarily determined by the extent of current efforts to control exposures in the plants rather than by plant size. The proposed regulation would tend to equalize competitiveness among plants by eliminating any economic advantage associated with inadequate engineering controls in some plants.

Table V-E8.—Costs of Compliance as Percentages of Revenues and Profits for Affected Industries Based on a 0.2 Mg/m ³ PEL for Asphalt Fume

DC, June 1990.

VI. Clearance of Information Collection Requirements

On March 31, 1983, the Office of Management and Budget (OMB) published a new 5 CFR Part 1320, implementing the information collection provisions of the Paperwork Reduction Act (PRA) of 1980, 44 U.S.C. 3501 et. sea. (48 FR 13666). Part 1320, which became effective on April 30, 1983, sets forth obtaining OMB clearance not later than the date of publication of the proposal in the Federal Register for collection of information requirements contained in proposed rules. It also requires agencies to include a statement in the notice of proposed rulemaking indicating that such information requirements have been submitted to OMB for review under section 3504(h) of the Paperwork Reduction Act.

In addition to the above requirements, applicable federal regulations also provide, 5 CFR 1320 4(a), 1320.5(a), and 1320.5(d), respectively, as follows:

An agency shall not engage in a collection of information without obtaining OMB approval of the collection of information and displaying a currently valid control number and, unless OMB determines it to be inappropriate, an expiration date.

Notwithstanding any other provision of law no person shall be subject to any

penalty for failure to comply with any information collection request if the request does not display a currently valid OMB control number, or, in the case of an information collection request which is submitted to nine or fewer persons, the request fails to state that for this reason it is not subject to OMB review under the Act.

Whenever a member of the public is protected from imposition of a penalty under this section for failure to comply with a collection of information, such penalty may not be imposed by an agency through judicial process, or by any other person through judicial or administrative process.

The proposed PELs update standard for Construction, Maritime, and Agriculture will create no additional recordkeeping requirements.

VII. Summary and Explanation of the Proposed Standard

Part 1926—Construction

Table Z, Construction in the standard includes proposed new permissible exposure limits for approximately 370 substances. Approximately 160 of the 370 are new PELs for substances which were not previously regulated. OSHA is proposing that the Z-Table in construction be identified as Table Z, Construction to indicate both its relation to and difference from Table Z-1-A for general industry. The substances listed on Tables Z-2 and Z-3 of 29 CFR part 1910 will be incorporated into the construction table, resulting in only one table for construction, Table Z. Construction.

Table Z, Construction is divided into two parts. On the left-hand side are the current (or transitional) limits, and on the right-hand side are the proposed limits for construction.

For construction, CFR part 1926.55 regulates exposure to gases, vapors, fumes, dusts, and mists, and references the "Threshold Limit Values of Airborne Contaminants for 1970" of the American Conference of Governmental Industrial Hygienists. These are the limits that currently exist and are enforced in construction.

The scope of many of the substancespecific OSHA health standards found in 29 CFR part 1910 includes coverage of the construction sector. Lead, § 1910.1025, and coke oven emissions, § 1910.1029, are the only substancespecific health standards specifying exposure limits that do not cover construction.

However, lead is covered in construction to the degree that the 1970 TLV for lead is 200 µg/m ³ TWA. And while the standard for coke oven emissions does not currently apply to construction, the coal tar pitch volatile TLV of 200 µg/m ³ TWA does apply.

OSHA is proposing, as part of this current rulemaking, a PEL of 50 µg/m 3 TWA for lead as an 8-hour TWA for construction. This is the level that has existed in general industry since 1978; this is also the level effective in the maritime sector. The ancillary provisions (e.g., medical surveillance, exposure monitoring) are outside the scope of this rulemaking. However, OSHA is currently developing a proposal to address all of the issues in a comprehensive standard covering workplace exposure to lead in the construction industry. OSHA is also proposing that the coke oven limit of 0.15 mg/m 3 (as found in § 1910.1029) apply to construction.

The policy reasons for this proposal are explained in part I of the preamble. The health bases for the new exposure limits are explained in part IV. The feasibility analysis for the proposal is summarized in part V. OSHA's preliminary findings that the proposed limits substantially reduce significant risk and are feasible, are based on these analyses.

In addition to Table Z, Construction, OSHA is proposing to both adopt some new language and to carry over some existing language from § 1926.55. Also, in some cases OSHA is proposing to

directly incorporate by technical amendment language currently applicable to construction by cross reference to the 1970 ACGIH TLVs.

The new language is in ¶ (a)(3), (a)(4), and (a)(5), which refer to compliance with the Final Rule Limits columns and to skin absorption. The language used is consistent with the language used in the General Industry standard. Also new is the language in ¶ (d) on start-up dates and transitional provisions. Comments are requested on all these provisions.

Substantially unchanged from prior provisions are ¶ (b) on Methods of Compliance and ¶ (c) on the Computation Formula. Paragraph (b) is a direct carryover from the existing § 1926.55(b). The Computation Formula is an existing provision already applicable to construction by cross reference to the 1970 ACGIH TLVs. Also [(a)(1) and (a)(2), covering Transitional Limits, are existing requirements applicable to construction by cross reference to the 1970 ACGIH TLVs. Substantive comments are not requested on ¶ (a)(1), (a)(2), (b), and (c), as these changes are technical amendments being made for the convenience of the public. The record is not being opened to consider substantive changes to these provisions. OSHA will consider comments suggestive of style change for the purpose of clarity.

The language in the proposed § 1926.55 (a) sets forth the obligation to protect employees from airborne and skin exposure. Airborne limits may be Time-Weighted Averages (TWA), Short Term Exposure Limits (STEL) and Ceilings (C). These are defined in

¶ (a)(5).

The standard states in § (a)(5):

(3) The following definitions apply to paragraph (a) of this section and Table Z. Construction;

(i) Time-weighted average (TWA) is the average airborne exposure of an employee in any 8-hour work shift of a 40-hour work week which shall not be exceeded.

(ii) Short term exposure limit (STEL) is the employee's 15-minute time-weighted average exposure which shall not be exceeded at any time during a work day. This applies even if the eight hour timeweighted average is within the TWA.

(iii) Ceiling is the employee's exposure which shall not be exceeded during any part of the work day. If instantaneous monitoring is not feasible, then the ceiling shall be assessed by sampling over a 15-minute period as would be done for a STEL, unless a different time period is specifically indicated.

In the current 29 CFR 1926.55(a), OSHA specifies that the exposure levels used in the "Threshold Limit Values of Airborne Contaminants for 1970" shall apply to construction. The 1970 TLVs include the computation formula for mixtures. Therefore, the reference to the 1970 TLVs has applied to construction the same Computation Formula that has applied to general industry as set forth in ¶ (d) of the General Industry Air Contaminants Final Rule. (See section I—H for further discussion.)

The standard provides an explanation of skin notation. In ¶ (a)(4) the standard

states:

An employee's skin exposure to materials listed in Table Z, Construction with an "S" notation shall be limited through the use of gloves, coveralls, goggles or other appropriate personal protective equipment or method necessary to prevent possible skin absorption.

Skin notations are used where the substance may be absorbed through the skin in sufficient amounts to cause systemic toxicity. As the standard's language indicates, appropriate personal protective equipment, engineering controls or work practices may also be used to minimize or eliminate skin contact in these situations. No specific hierarchy of controls is mandated for the prevention of skin contact. (See also discussion under VI. Health Effects Discussion, C. 17, Substances for Which OSHA is Adding Skin Notations.)

It should be noted that upon the effective date for the proposed new standard, OSHA is proposing that the Skin Designation in the Final Rule Limits columns becomes applicable.

Consequently the Skin designation in the Transitional Limits Columns will no longer have effect after the effective

date unless a stay is issued.

OSHA recognizes that it takes time for employers to evaluate exposures and purchase, install and make operable equipment to control such exposures. OSHA believes that 3 months from the date of publication is a reasonable time to evaluate exposures and come into compliance with any reasonable combination of controls. OSHA is proposing 4 years as the time to come into compliance with a preference for engineering controls. Comment on these start-up dates is requested.

The purpose of the Transitional Limits is to state the limits to be achieved by primary reliance on engineering controls, if feasible, during the 4 year transitional period. During the transitional period the new limits may be achieved by any reasonable combination of engineering, work practice and respiratory controls. This priority on compliance with engineering controls as set forth in § 1926.55 (b) for the exposure limits in the Transitional

Limit Columns is the existing requirement. The exposure limits in the Transitional Limits columns also would remain in place if any of the new limits are stayed.

OSHA is not proposing to change limits in this rulemaking for 9 substances for which comprehensive rulemakings are in progress, or NPRMs have been published. These substances are cadmium (dust and fume), butadiene, ethylene dibromide, methylene chloride and two glycol ethers and their acetates. As OSHA has made substantial progress towards developing a comprehensive standard for these substances, it would be wasteful of resources to consider these substances in the current proceeding.

Complete and published proposed rules are available for cadmium (dust and fume), butadiene, ethylene dibromide and methylene chloride. For those substances for which a proposal has been published, the proposed PEL is located in the Proposed Final Rule columns in each Z-table. If a proposal has not been published for a specific substance, then the existing limit is reflected in the table. OSHA intends to carry over the PELs established in these separate substance-specific rulemakings to the Z-tables. OSHA wishes to make clear that it is not opening the record on any substance for which separate rulemaking is in progress.

In reference to ethylene dibromide, an NPRM was published in 1983, and a final rule has not been published. As EDB is no longer produced in the U.S., OSHA has given the substance low priority. Therefore, the present limits are

listed in the Z-tables.

The language of this proposal follows the format shown to and approved by the Construction Advisory Committee. The style of this proposal differs from that of general industry and maritime. This difference is reflected primarily in the introductions to ¶ 1926.55(a), 1915.1000(a), and 1910.1000. OSHA believes there are advantages in following the same style across all sectors as much as is possible. OSHA is considering changing the format in construction to more closely follow the format in other sectors. OSHA requests comment on this.

Part 1915-Shipyards

OSHA consulted with the Shipyards Advisory Committee on the Air Contaminants Standard for Shipyards at its May and August 1991 meetings. The content and format of the regulatory language in part reflects the result of these consultations. The committee is generally supportive of the proposal.

The Committee believes that the Shipyard regulations in general should become more self-contained with less need for cross-reference to General Industry standards. They also suggested that placing health regulations in their own Subpart Z for shipyards and maintaining consistency of definitions and regulatory language with the 1989 PELs would make these regulations easier to understand. OSHA agrees with these suggestions.

Accordingly, OSHA is proposing that there be a new Subpart Z for Part 1915 Shipyards which contains a § 1915.1000 Air Contaminants. That section includes a Table Z, Shipyards which lists all of the permissible exposure limits (PELs)

applicable to Shipyards.

Table Z, Shipyards incorporates PELs from 4 sources. Approximately 370 PELs that are either new or more protective than the old limits are being proposed in Shipyards. Approximately 210 PELs will remain unchanged. Approximately 15 substances are currently covered in Shipyards through cross-reference to single substance standards in 29 CFR 1910.1001-1048. They are listed in the table with the exposure limit and a cross-reference to the ancillary provisions of the single substance standard. Finally, there are two substances (coke oven emissions and cotton dust) that have been applied to general industry but have not been specifically applied to Shipyards. OSHA is proposing that the exposure limits for cotton dust be made applicable to Shipyards. Table I-F lists the substances which OSHA is either newly proposing for shipyards or is proposing more protective limits. OSHA is only opening the record for these substances.

Table Z, Shipyards lists all the substances for which OSHA has either existing or proposed PELs. Table Z. Shipyards is divided into Transitional Limit columns on the left and Proposed Final Rule Limit columns on the right. The Proposed Final Rule Limit columns include all the proposed exposure limits applicable to shipyards and all the existing exposure limits which are not being included in this rulemaking. The Proposed Final Rule Limit has columns which set forth the 8-hour TWA limit, the STEL limit, and the Ceiling limit, if applicable. The last column indicates whether there is skin designation. These terms are defined in § 1915.1000(a).

The Transitional Limit columns state the existing exposure limits which are applicable to ship repairing and shipbreaking based on the 1970 TLVs. As explained in the Legal Authority section, the existing exposure limits for shipbuilding are slightly different since they are based on the 1971 PELs. Since the anomaly is confusing and has no

health basis, OSHA is proposing that on the effective date of this standard, the Transitional Limits for shipbuilding be identical with those for ship repairing and shipbreaking. To facilitate this transition, Table Z, Shipyards has already been organized to incorporate this change.

The purpose of the Transitional Limits is to state the limits to be achieved by primary reliance on engineering controls, if feasible, during the 4 year transitional period. During the transitional period the new limits may be achieved by any reasonable combination of engineering, work practice and respiratory controls. This priority on compliance for engineering controls as set forth in § 1915.1000(c) for the exposure limits in the Transitional Limit Columns is the existing requirement. The exposure limits in the Transitional Limits columns also would remain in place if any of the new limits are stayed.

It should be noted that upon the effective date for the proposed new standard, OSHA is proposing that the Skin Designation in the Final Rule Limits columns becomes applicable.

Consequently the Skin designation in the Transitional Limits Columns will no longer have effect after the effective

date unless there is a stay.

The substantive paragraphs of the proposed § 1915.1000 include the same concepts as the 1989 PELs for General Industry, and the same concepts as proposed for Construction, Longshoring and Marine Terminals. Pursuant to ¶ (a), an employee's exposure to substances listed in Table Z, Shipyards shall be kept below the limits specified in Table Z. It is the employer's responsibility to take steps to keep employee exposure below the limits.

The airborne limits for employee exposure may be an 8 hour Time Weighted Average (TWA), a Short Term Exposure Limit (STEL) or a Ceiling Limit, or in some cases a TWA and a STEL or a Ceiling. Those terms are defined in ¶ (a)(3) as follows:

(i) Time weighted average (TWA) is the employee's average airborne exposure in any 8-hour shift of a 40-hour work week which shall not be exceeded.

(ii) Short term exposure limit (STEL) is the employee's 15-minute time weighted average exposure which shall not be exceeded at any time during a work day unless another time limit is specified in a parenthetical notation below the limit. If another time period is specified, the time weighted average exposure over that time period shall not be exceeded at any time during the working day.

(iii) Ceiling is the employee's exposure which shall not be exceeded during any part of the work day. If instantaneous monitoring is not feasible, then the ceiling shall be assessed as a 15-minute time weighted

average exposure which shall not be exceeded at any time over a working day.

When there is an "X" in the Skin designation column, then skin exposure shall be prevented or reduced to prevent skin absorption. Skin notations are used where the substance may be absorbed through the skin in sufficient amounts to cause systemic toxicity. As the standard's language indicates, appropriate personal protective equipment, engineering controls or work practices may also be used to minimize or eliminate skin contact in these situations. No specific hierarchy of controls is mandated for the prevention of skin contact. (See also discussion under VI. Health Effects Discussion, C. 17, Substances for Which OSHA is Adding Skin Notations.)

Paragraph (b) provides the computation formula if an employee is exposed to more than 1 toxic substance at one time. It is applicable if the employee is exposed to toxic substances affecting the same organ or causing the same disease. It permits the computation of maximum exposures in such circumstances when there are simultaneous exposures to several toxic substances. The computation formula is already applicable to ship repair and shipbreaking by their incorporation of the 1970 TLVs and to shipbuilding through the 1971 TLVs. OSHA is not opening the computation formulae for comment. (See Section I-H for further discussion.)

Paragraph (c) sets forth methods of compliance with a preference for feasible engineering and work practice controls. This paragraph states an existing requirement which already applies to Shipyards through the 1970 TLVs or the 1971 PELs. OSHA is not opening methods of compliance for comment in this proceeding as OSHA is in the process of completing a separate rulemaking on methods of compliance.

Paragraph (d) sets forth proposed effective and start-up dates. The proposed effective date is 90 days after publication in the Federal Register of the final rule pursuant to statute (section 6(b)4)). The Shipyard Advisory Committee indicated that they were familiar with the new exposure limits and it would save confusion if they were made applicable without delay. Accordingly OSHA is proposing that the new PELs take effect on the effective date with compliance with any reasonable combination of work practices, engineering controls or respirators. OSHA is also proposing, pursuant to the Committee's recommendation that the start-up date to come into compliance with a preference for feasible engineering

controls pursuant to ¶ (c) be 4 years after publication of the final rule in the Federal Register. OSHA requests comments on these start-up dates.

Paragraphs (d)(3) covers the Transitional Limits which are discussed above. Paragraph (d)(4) covers stays, if any, issued after the final rule is published. It provides that if a new limit is stayed, the prior (Transitional Limit) remain in effect.

A number of amendments to part 1915 are necessary to maintain consistency with other sectors. It is not OSHA's intention, by these proposed consequential amendments, to change other concepts in the Shipyards standards except to make clear that the Air Contaminants exposure limits are applicable to all employees and operations in the Shipyard industry.

OSHA is accordingly proposing to delete all references to the 1970 TLVs and replace them where necessary with reference to the proposed 29 CFR part 1915, subpart Z. These proposed amendments are made to §§ 1915.5, 1915.12(a)(3), 1915.12(b)(3) and 1915.32(b). However OSHA is not proposing changes to the provisions of § 1915.12 which require in certain circumstances pre-entry inspection prior to entry into holds, compartments and various areas where a build up of toxic substances may occur and various precautions must be taken.

There are nine substances for which OSHA has either published an NPRM or is otherwise engaged in rulemaking. The disposition of the PELs for those substances in regard to this rulemaking is discussed at greater length at the end of the discussion on the Summary and Explanation of the proposed Construction standard. (See VII. Summary and Explanation of the Proposed Standard, part 1926—Construction.) OSHA wishes to make it clear that it is not opening the record for any substance for which comprehensive rulemaking is in progress.

Parts 1917—Marine Terminals, and Part 1918—Longshoring

Table Z, Longshoring and Marine
Terminals includes proposed
permissible exposure limits (PELs) for
approximately 370 new or more
protective PELs in the Maritime
subsectors of Marine Terminals and
Longshoring. OSHA is proposing today a
1917 subpart Z for Marine Terminals
(§ 1917.1000) and a 1918 subpart Z for
Longshoring (§ 1918.1000).

As both sectors have identical Transitional and Final Rule exposure limits, OSHA is proposing to publish only one Z Table for both subsectors, Table Z, Longshoring & Marine Terminals. OSHA is proposing that the table be printed only once and that it be located in part 1917 after § 1917.1000. It will be cross-referenced in § 1918.1000. OSHA believes that this will not create an inconvenience or confusion to the public or as parts 1917 and 1918 are invariably published together. There is some saving of space and cost to the government by following this approach. Comments are requested on it.

The proposed new Table Z,
Longshoring & Marine Terminals, and
\$ 1917.1000 and \$ 1918.1000 are
conceptually similar to the parallel
provisions of part 1915. Accordingly, the
discussions of those part 1915 provisions
are applicable here and will not be
repeated. Instead the differences and
the different consequential provisions
are discussed. See also the Legal
Authority section of the preamble for
the historical background of these
distinctions.

The Final Rule limit columns of Table Z, Marine Terminals and Longshoring are identical to the same columns on Table Z, Shipyards. The Transitional Limits columns are different for approximately 30 substances. This is because the existing limits for Longshoring and Marine Terminals are based on the 1971 OSHA PELs whereas the existing limits for Shipyards are based on the 1970 TLVs. (See the above discussion of Shipyards for a further explanation.)

Some of the provisions of parts 1917 and 1918 are unique due to the nature of the original provisions in these two parts and to the special concern for confined spaces in holds, compartments, vehicles, warehouses etc. Also these sectors often handle intact sealed containers. OSHA's proposed intention is to make the Air Contaminant limits generally applicable to all operations in Marine Terminals and Longshoring with exceptions for intact sealed, containers and carbon monoxide while retaining the existing unique provisions of parts 1917 and 1918 to the extent they are not inconsistent with the air contaminants

Intact, sealed containers of toxic substances which are often handled in marine terminals and longshore operations, by definition, do not present the hazard of airborne exposure or skin contact with toxic substances. Part 1917 in § 1917.1(a)(2)(ii) currently provides that the air contaminant limits do not apply when a substance or cargo is contained within a sealed, intact means of packaging or containment complying with Department of Transportation or International Maritime Organization requirements. OSHA is proposing to retain this provision and formally

incorporate it into part 1918. As long as toxic substances are properly contained there will not be exposure.

However, containers can be damaged in the course of cargo handling, resulting in the possibility of leakage and employee exposure. Consequently, OSHA is proposing language that specifies that should cargo containers become damaged to the extent that the possibility for leakage exists, then the Air Contaminant exposure limits apply. However, as these circumstances will be in the nature of accidents or emergencies, any reasonable combination of engineering controls. work practice and personal protective equipment is permitted as the method of compliance. The proposed language for these provisions is located in § 1917.1000(d) and § 1918.1000(d).

Because of the dangers of death from carbon monoxide poisoning in the confined spaces of holds, vehicles, rail cars and poorly ventilated warehouse spaces where workers in marine terminals and longshoring frequently work, parts 1917 and 1918 have detailed protective provisions located in § 1917.24 and § 1918.93(a). These sections have testing provisions and a requirement that employees be removed when carbon monoxide exposure exceeds 100 ppm in a confined space. Because of the difficulty of observing employees in confined spaces, the difficulty of escaping from them and the unfortunate occurrence of death to persons attempting to rescue persons disabled in confined spaces, these protective provisions are appropriate. OSHA is retaining those provisions but is proposing to lower the 8 hour TWA for carbon monoxide for these sectors from 50 ppm to 35 ppm and apply a 200 ppm ceiling measured over 5 minutes to open spaces. These limits are consistent with OSHA's final determination for general industry. See the health write-up for carbon monoxide.

Paragraph (b) provides the computation formula if an employee is exposed to more than 1 toxic substance at one time. It is applicable if the employee is exposed to toxic substances affecting the same organ or causing the same disease. It permits the computation of maximum exposures in such circumstances when there are simultaneous exposures to several toxic substances. The computation formula is already applicable to longshoring and marine terminals by reference to 1910.1000. OSHA is not opening the computation formulae for comment. (See Section I-H for further discussion.)

Part 1917 has certain unique provisions on hazardous cargo—

§ 1917.22, pesticides-§ 1917.25, menhaden (a species of fish) terminals-1917.73, welding and hot work-1917.152 and spray painting § 1917.153. These are being retained. However, § 1917.23(a) is proposed to be amended to clearly indicate that the air contaminant exposure levels are always applicable.

There are nine substances for which OSHA has either published an NPRM or is otherwise engaged in rulemaking. The disposition of the PELs for those substances in regard to this rulemaking is discussed at greater length at the end of the discussion on the Summary and Explanation of the proposed Construction standard. (See VII. Summary and Explanation of the Proposed Standard, part 1926-Construction.)

OSHA is proposing that the new air contaminant exposure limits take effect 90 days after the publication of the final rule with any reasonable combination of controls and 4 years after publication with a preference for engineering controls for Marine Terminals and Longshoring. OSHA requests comment on these dates.

Part 1928—Agriculture

Table Z. Agriculture includes proposed permissible exposure limits (PELs) for approximately 600 substances that have not previously been regulated in agriculture. OSHA is proposing that the Z-Table in agriculture be identified as Table Z, Agriculture to indicate both its relation to and difference from Table Z-1-A for General Industry. All of the limits that would apply in agriculture are shown in this single table, i.e., in Table Z, Agriculture. There is no transitional limit column in Table Z, Agriculture because OSHA PELs have not previously applied in agriculture.

When OSHA published its Air Contaminants Final Rule for general industry on January 19, 1989 (54 FR 2332 et seq.), the Agency stated:

OSHA has also determined that it is appropriate to limit this rulemaking to the General Industry sector. Application to the Construction, Maritime & Agriculture segments may require some modifications to this proposed rule because of differences in exposures and work situations in the established PELs for these segments, and differences regarding feasibility for these sectors. OSHA will pursue this as part of second stage rulemaking

The limits being proposed in agriculture today constitute part of that second stage of rulemaking. In the prior rulemaking for general industry, OSHA reduced the PELs for 212 substances and set new PELs for 164 substances previously not regulated by OSHA. The PELs being proposed today in Table Z,

Agriculture include the 378 new limits that were promulgated in this earlier rulemaking. In addition, Table Z, Agriculture, proposes PELs for approximately 160 substances which were previously regulated by OSHA in general industry since 1970 but whose limits were not changed in the 1989 rulemaking. These 160 substances are being regulated in agriculture for the first time, and are included in Table 1-F.

There are another 52 or so substances for which OSHA had considered a change in the PEL in the proposal for general industry, but for which none was made in the final rule. Regulation of these 52 substances is also being

proposed in agriculture.

To ensure consistency in the protection afforded to workers across sectors, OSHA is also proposing PELs in agriculture for 10 of the 24 substances the Agency has regulated in comprehensive 6(b) rulemaking proceedings (see §§ 1910.1000 to 1910.1047) which have numerical exposure limits as part of the standard. These limits have previously been issued in section 6(b) rulemakings. The health effects and feasibility of OSHA's PELs have been fully considered. These findings are summarized in Section IV.C of this preamble. These ten substances are asbestos, vinyl chloride, inorganic arsenic, lead, benzene, cotton dust, DBCP, acrylonitrile, ethylene oxide and formaldehyde.

OSHA is not proposing to change limits for 9 substances for which the Agency is currently conducting comprehensive section 6(b) rulemakings are in progress because the appropriate PELs for these substances will not be determined until their respective final rules are published. OSHA is not opening the record in the present air contaminants rulemaking for construction, maritime, or agriculture for any substance that is currently undergoing separate rulemaking. Once these rulemakings are completed, OSHA will add the respective PELs to all of the Z tables.

The policy reasons for this proposal are explained in part I of the preamble. The health basis of the new exposure limits are explained in part IV and feasibility analysis for the proposal is summarized in part V. OSHA's preliminary conclusion that the proposed limits noted in Table Z. Agriculture, substantially reduce significant risk among workers in agriculture and are feasible in this sector are based on the analyses summarized in those sections of the

In addition to the Table Z, Agriculture, OSHA is also proposing to adopt language similar to that in \ (a) of § 1910.1000 and include it in part 1928. That language sets forth the obligation of agricultural employers to protect employees from overexposures to airborne contaminants and toxic substances that cause systemic toxicity when absorbed through the skin. Airborne limits may be expressed as Time-Weighted Averages (TWAs), Short Term Exposure Limits (STELs) and Ceilings (Cs). These are defined as follows in paragraph (a)(3) of the standard:

(i) Time Weighted Average (TWA) is the average airborne exposure of an employee in any 8-hour work shift of a 40-hour work week which shall not be exceeded.

(ii) Short term exposure limit (STEL) is the employee's 15-minute time-weighted average exposure which shall not be exceeded at any time during a work day. This applies even if the eight hour timeweighted average is within the TWA.

(iii) Ceiling is the employee's exposure which shall not be exceeded during any part of the work day. If instantaneous monitoring is not feasible, then the ceiling shall be assessed by sampling over a 15-minute period as would be done for a STEL, unless a different time period is specifically indicated.

The standard provides an explanation of skin notation. In ¶ (a)(2) the standard

An employee's skin exposure to materials listed in Table Z. Agriculture. with an "S" Notation shall be limited through the use of gloves, coveralls, goggles or other appropriate personal protective equipment or method necessary to prevent possible skin absorption.

Skin notations are used where the substance may be absorbed through the skin in sufficient amounts to cause systemic toxicity. As the standard's language indicates, appropriate personal protective equipment, engineering controls or work practices may also be used to minimize or eliminate skin contact in these situations. No specific hierarchy of controls is mandated for the prevention of skin contact. (See also discussion under VI. Health Effects Discussion, C. 17, Substances for Which OSHA is Adding Skin Notations.)

OSHA is proposing, in paragraph (b). to apply the Computation (or Mixture) Formula to agriculture. See section I-H

for further discussion.

OSHA recognizes that it takes time for employers to evaluate exposures and to purchase, install and make operable equipment to control such exposures. OSHA believes that 1 year from the date of publication is a reasonable time to evaluate exposures and come into

compliance with any combination of respirators, work practices and engineering controls for agriculture. This is longer than OSHA normally provides, but as no exposure limits previously applied in agriculture, more time may be necessary for agricultural employers to become familiar with the regulations, determine employee exposures, and institute controls. Four years are provided for coming into compliance with a preference for engineering controls. Comment on these start-up dates is requested.

With regard to proposed § 1910.1000(c), methods of compliance, OSHA recognizes that engineering controls that are typically used in industrial applications have not been regularly adapted to the agricultural setting. However, simple controls, such as placing lids on containers, have been used in agriculture. Although OSHA recognizes that agriculture may lag behind other sectors with regard to the use of engineering controls, industrial hygiene sampling, etc., the Agency expects that experience with this regulation will parallel OSHA's experience in the past and that use of technology and industrial hygiene approaches will occur over a reasonable period of time.

The four-year period of time before compliance with engineering controls will permit knowledge of appropriate technology to become known to the farming community. OSHA and NIOSH intend to engage in extensive outreach to inform agricultural employers of appropriate technology to control exposures on farms.

The purpose of this approach is to allow OSHA to assure safe and healthy work sites for workers in agriculture, while maintaining a role which includes education as well as enforcement. This approach is consistent with OSHA's activity and goals in agriculture. As literature and training become more widely available, the agricultural employer will be expected to have access to that knowledge.

VIII. Public Participation-Public Hearings

Interested persons are invited to submit written data, views, and arguments with respect to OSHA'S proposed rule. These comments must be postmarked on or before September 25, 1992, and submitted in quadruplicate to the Docket Officer, Docket H–020A, room N–2625, U.S. Department of Labor, Washington, DC 20210, Tel. (202) 523–7894.

This rulemaking covers a large number of substances and industries. Therefore, to permit the public and OSHA to efficiently review the comments, it is necessary to specify the format of the comments in greater detail than normally required for OSHA rulemaking.

Comments on the general concept of the proposal shall be first and shall begin on a new page with the heading "General Comments", the name of the commenter, and the commenter's SIC code or codes if a business.

Comments on individual substances shall follow. The comment on each substance shall start on a new page with a heading identifying the substance with the name and code number used in Table I-G (the HS code number) of the preamble; (not the CAS number) and a second line identifying the comment as on "Health Issues" or on "Feasibility Issues." If there are comments on both they shall begin on separate pages with headings that identify the substances, and its code number and area of the comment. For feasibility comments, the heading should contain a third line identifying the SIC codes (preferably 4 digit) that the comment covers.

In addition the first or second page of each comment is to have a table of contents indicating the page number that the general comments begin and the page number that Health and Feasibility comments for each chemical individually discussed begin. Finally, one of the four sets of each comment received should not be stapled or bound, so that it can be easily copied. Written submissions must clearly identify the specific provisions of the proposal which are addressed and the position taken with respect to each issue.

The data, views and arguments that are submitted will be available for public inspection and copying at the above address. All timely submissions received will be made a part of the record of this proceeding. The exhibits cited in this document will be available for public inspection and copying at the above address.

In addition, the record and the record of the General Industry rulemaking Docket No. H–020 currently contains many data bases of economic and health information. That information is also available for inspection and copying at the Docket Office. (Much of the information is on computer tape. OSHA will supply duplicate tapes for the copying charge.)

Notice of Intention To Appear at the Informal Hearing

Pursuant to section 6(b)(3) of the OSHA Act, informal public hearings will be held on this proposal in Washington, DC from Tuesday, October 20, 1992 through Friday, October 30, 1992; in San Diego from Tuesday, November 17, 1992 through Friday, November 20, 1992; and in Des Moines from Tuesday, December 8, 1992 through Friday, December 11, 1992. In each city if testimony is less extensive the hearing may terminate earlier and if more extensive it may be extended.

The Washington hearing will commence at 9:30 a.m. in the auditorium of the Frances Perkins Building, U.S. Department of Labor, 3d Street and Constitution Avenue NW., Washington, DC 20210.

The hearing in San Diego will be at the Holiday Inn on the Bay, 1355 North Harbor Drive, San Diego, California, 92101, Tel: (619) 232–3861.

The hearing in Des Moines will be at the Holiday Inn Des Moines, 1050 Sixth Ave., Des Moines, Iowa, 50314, Tel: [515] 283-0151.

Persons desiring to participate at the informal public hearing must file a notice of intention to appear by September 11, 1992. The notice of intention to appear must contain the following information:

- 1. The name, address, and telephone number of each person to appear;
- 2. The capacity in which the person will appear;
- 3. The approximate amount of time required for the presentation;
- 4. The issues and substances that will be addressed;
- 5. A brief statement of the position that will be taken with respect to each issue and substance addressed; and
- Whether the party intends to submit documentary evidence and, if so, a brief summary of it.
- 7. The city or cities where the participant wishes to testify. Repetitive testimony in different cities is not permitted.

The Notice of Intention to Appear shall be mailed to Mr. Thomas Hall, OSHA Division of Consumer Affairs, Docket No. H-020, U.S. Department of Labor, room N-3647, 200 Constitution Avenue, NW., Washington, DC 20210, telephone (202) 523-8615, and shall be postmarked no later than September 11, 1992.

A notice of intention to appear also may be transmitted by facsimile to (202) 523–5986 or (for FTS) to 8–523–5986, by the same date provided the original and 3 copies are sent to the same address and postmarked no later than 3 days later.

Filing of Testimony and Evidence Before the Hearing

Any party requesting more than ten (10) minutes for presentation at the informal public hearing, or who intends to submit documentary evidence, must provide in quadruplicate the testimony and evidence to be presented at the informal public hearing. The documentary evidence and testimony shall follow the format and include the headings and index required for comments. One copy shall not be stapled or bound and be suitable for copying. These materials must be provided to Mr. Thomas Hall, OSHA Division of Consumer Affairs at the address above and be postmarked no later than September 25, 1992.

Each submission will be reviewed in light of the amount of time requested in the Notice of Intention to Appear. In instances where the information contained in the submission does not justify the amount of time requested, a more appropriate amount of time will be allocated and the participant will be notified of that fact prior to the informal

public hearing.

Any party who has not substantially complied with the above requirement may be limited to a ten-minute presentation and may be requested to return for questioning at a later time.

Any party who has not filed a notice of intention to appear may be allowed to testify for no more than 10 minutes as time permits, at the discretion of the Administrative Law Judge, but will not be allowed to question witnesses.

Notice of intention to appear, testimony and evidence will be available for inspection and copying at the Docket Office at the address above.

Conduct and Nature of Hearings

The hearings will commence at 9:30 a.m. on the first day in each city. At that time, any procedural matters relating to the proceeding will be resolved.

The nature of an informal rulemaking hearing is established in the legislative history of section 6 of the OSH Act and is reflected by OSHA's rules of procedure for hearings (29 CFR 1911.15(a)). Although the presiding officer is an Administrative Law Judge and questioning by interested persons is allowed on crucial issues, the proceeding is informal and legislative in type. The Agency's intent, in essence, is to provide interested persons with an opportunity to make effective oral presentations which can proceed expeditiously in the absence of procedural restraints which impede or protract the rulemaking process.

Additionally, since the hearing is primarily for information gathering and clarification, it is an informal administrative proceeding rather than an adjudicative one. The technical rules of evidence, for example do not apply. The regulations that govern hearings

and the pre-hearing guidelines to be issued for this hearing will ensure fairness and due process and also facilitate the development of a clear, accurate and complete record. Those rules and guidelines will be interpreted in a manner that furthers that development. Thus, questions of relevance, procedure and participation generally will be decided so as to favor development of the record.

The hearing will be conducted in accordance with 29 CFR part 1911. It should be noted that § 1911.4 specifies the Assistant Secretary may upon reasonable notice issue alternatives procedures to expedite proceedings or for other good cause. The hearing will be presided over by an Administrative Law Judge who makes no decision or recommendation on the merits of OSHA's proposal. The responsibility of the Administrative Law Judge is to ensure that the hearing proceeds at a reasonable pace and in an orderly manner. The Administrative Law Judge, therefore, will have all the powers necessary and appropriate to conduct a full and fair informal hearing as provided in 29 CFR part 1911 including the powers:

To regulate the course of the proceedings:

2. To dispose of procedural requests, objections and comparable matters;

To confine the presentations to the matters pertinent to the issues raised;

 To regulate the conduct of those present at the hearing by appropriate means;

 In the Judge's discretion, to question and permit the questioning of any witness and to limit the time for questioning; and

6. In the Judge's discretion, to keep the record open for a reasonable, stated time (known as the post hearing comment period) to receive written information and additional data, views and arguments from any person who has participated in the oral proceedings.

State Plan Applicability

The 25 states with their own OSHAapproved occupational safety and health plans must adopt a comparable standard within six months of the publication date of a final standard. These States include: Alaska, Arizona, California, Connecticut (for State and local government employees only), Hawaii, Indiana, Iowa, Kentucky, Maryland, Michigan, Minnesota, Nevada, New Mexico, New York (for State and local government employees only), North Carolina, Oregon, Puerto Rico, South Carolina, Tennessee, Utah, Vermont, Virginia, Virgin Islands, Washington, Wyoming. Until such time as a State standard is promulgated, Federal OSHA will provide interim enforcement assistance, as appropriate,

List of Subjects

29 CFR Part 1910

Air contaminants, Occupational safety and health. Permissible exposure limits, Health, Risk assessment, Construction, Maritime, Shipyards, Longshoring, Marine terminals, Agriculture.

29 CFR Part 1915

Air contaminants, Hazardous substances, Longshore and harbor workers, Occupational safety and health, Permissible exposure limits, Vessels.

29 CFR Part 1917

Air contaminants, Hazardous substances, Longshore and harbor workers, Occupational safety and health, Permissible exposure limits.

29 CFR Part 1918

Air contaminants, Freight, Hazardous substances, Longshore and harbor workers, Occupational safety and health, Permissible exposure limits, Vessels.

29 CFR Part 1926

Air contaminants, Construction industry, Hazardous substances, Occupational safety and health, Permissible exposure limits.

29 CFR Part 1928

Air contaminants, Agriculture, Occupational safety and health, Permissible exposure limits.

IX. Authority

This document has been prepared under the direction of Dorothy L. Strunk, Acting Assistant Secretary of Labor for Occupational Safety and Health, U.S. Department of Labor, 200 Constitution Avenue NW., Washington, DC 20210. Pursuant to section 6 of the Occupational Safety and Health Act of 1970 (29 U.S.C. 655), section 4 of the Administrative Procedures Act (5 U.S.C. 551), 29 CFR part 1911 and Secretary of Labor's Orde. No. 1–90 (55 FR 9033), it is proposed to amend 29 CFR parts 1910, 1915, 1917, 1918, 1926 and 1928 as set forth below.

Signed at Washington, DC., this 29 day of May, 1992.

Dorothy L. Strunk,

Acting Assistant Secretary of Labor.

X. Standard

OSHA proposes to amend 29 CFR part 1910, subpart Z as follows:

PART 1910-OCCUPATIONAL SAFETY AND HEALTH STANDARDS

1. The authority citation for Subpart Z continues to read in part as follows:

Authority: Secs. 6, 8 Occupational Safety and Health Act, 29 U.S.C. 655, 657: Secretary of Labor's Orders 12-71 (36 FR 8754), 8-76 (41 FR 25059), 9-83 (48 FR 35736) or 1-90 (55 FR 9033), as applicable; and 29 CFR part 1911.

All of subpart Z issued under section 6(b) of the Occupational Safety and Health Act, 29 U.S.C. 655(b) except those substances listed in the Final Rule Limits columns of Table Z-1-A, which have identical limits listed in the Transitional Limits columns of Table Z-1-A, Table Z-2 or Table Z-3. The latter were issued under section 6(a) (29 U.S.C. 655(a)).

Section 1910.1000, the Transitional Limits columns of Table Z-1-A, Table Z-2 and Table Z-3 also issued under 5 U.S.C. 553, § 1910.1000, the Transitional Limits columns of Table Z-1-A, Table Z-2 and Table Z-3 not issued under 29 CFR part 1911 except for the arsenic, benzene, cotton dust, and

formaldehyde listings.

2. It is proposed to amend § 1910.1000 by adding a new paragraph (f)(5) to read as follows:

§ 1910.1000 Air contaminants. 4 4 4

(f) Effective dates, start-up dates and transitional provisions

(5) For the exposure limits for asphalt, fiberglass and mineral wool the effective date shall be [90 days after the date of publication of final rule in the Federal Register], the start-up date for compliance through any reasonable combination of engineering controls work practices and personal protective equipment shall be (6 months after the date of publication of the final rule in the Federal Register) and the start-up date for compliance using the methods of compliance specified in paragraph (e) of this section shall be (2 years after the date of publication in the Federal Register).

3. It is proposed to amend § 1910.1000, Table Z-1-A by inserting new entries as

(a) After the entry for Asbestos insert into the Substance column the entry "Asphalt fumes (total particulate)". insert in the CAS No. column "8052–42– 4" and insert in the Final rule limits. TWA, mg/m3 column the entry "5"

(b) After the entry for Ferrovanadium dust, insert into the Substance column the entry "Fibrous glass" and insert into the Final rule limits, TWA, columns the

entry "1 f/cc".

(c) After the entry for Mica, insert into the Substance column the entry "Mineral wool" and insert into the Final rule limits, TWA, columns the entry "1 f/cc".

OSHA proposes to amend 29 CFR parts 1915, 1917, 1918, 1926 and 1928 as follows:

I. OSHA proposes to amend 29 CFR part 1915 as follows:

PART 1915—SHIPYARDS

1. It is proposed to revise the authority citation for part 1915 to read as follows:

Authority: Sec. 41, Longshore and Harbor Workers Compensation Act (33 U.S.C. 941); secs 4, 6, 8, Occupational Safety and Health Act of 1970 (29 U.S.C. 653, 655, 657); Secretary of Labor's Order No. 12-71 (36 FR 8754), 8-76 (41 FR 25059), 9-83 (48 FR 35736) or 1-90 (55 FR 9033), as applicable: 29 CFR Part 1911.

Section 1915.99 also issued under 5 U.S.C.

§ 1915.5 [Amended]

2. It is proposed to amend § 1915.5 by removing the paragraph which reads:

Threshold Limit Values, 1970. American Conference of Governmental Industrial Hygienists, 1014 Broadway, Cincinnati, Ohio 45202, Subpart B, § 1915.12 (a)(3) and (b)(3); Subpart C, § 1915.32(b).

3. It is proposed to amend § 1915.12 by revising paragraphs (a)(3) and (b)(3) to read as follows:

§ 1915.12 Precautions before entering.

(a) Flammable atmospheres and residues.

(3) If the atmosphere in the space to be entered is found to contain a concentration of flammable vapor or gas below the level immediately dangerous to life as defined in § 1915.152(b)(1), but above the permissible exposure limits specified in 29 CFR 1915, subpart Z, employees shall be protected in accordance with the requirements of 29 CFR 1915, subpart Z.

(b) Toxic atmospheres and residues.

(3) If the atmosphere in the space to be entered is found to contain a concentration of toxic contaminants below the level immediately dangerous to life as defined in § 1915.152(b)(1), but above the permissible exposure limits specified in 29 CFR 1915, subpart Z, employees shall be protected in accordance with the requirements of 29 CFR 1915, subpart Z.

4. It is proposed to amend § 1915.32 by revising paragraph (b) to read as

§ 1915.32 Toxic cleaning solvents.

(b) The requirements of 29 CFR 1915. subpart Z shall be followed.

Subparts M-Y-[Reserved]

5. It is proposed to reserve subparts M-Y and to add a new subpart Z consisting of § 1915.1000 to read as

Subpart Z—Toxic and Hazardous Substances

§ 1915.1000 Air contaminants.

(a) Exposure limits. An employee's exposure to any substance listed in Table Z, Shipyards shall be limited in accordance with the requirements of the following paragraphs of this section:

(1) Final Rule Limits Columns. An employee's exposure to any substance listed in Table Z. Shipvards shall not exceed the Time Weighted Average (TWA), Short Term Exposure Limit (STEL) and Ceiling Limit specified for that substance in Table Z under the Final Limits columns.

(2) Skin Designation. To prevent or reduce skin absorption, an employee's skin exposure to substances listed in Table Z, Shipyards with an "X" in one or both of the Skin Designation columns following the substance name shall be prevented or reduced to the extent necessary in the circumstances through the use of gloves, coveralls, goggles, or other appropriate personal protective equipment, engineering controls or work practices.

(3) Definitions. The following definitions are applicable to Table Z. Shipyards:

(i) Time weighted average (TWA) is the employee's average airborne exposure in any 8-hour work shift of a 40-hour work week which shall not be exceeded.

(ii) Short term exposure limit (STEL) is the employee's 15-minute time weighted average exposure which shall not be exceeded at any time during a work day unless another time limit is specified in a parenthetical notation below the limit. If another time period is specified, the time weighted average exposure over that time period shall not be exceeded at any time during the working day.

(iii) Ceiling is the employee's exposure which shall not be exceeded during any part of the work day. If instantaneous monitoring is not feasible, then the ceiling shall be assessed as a 15-minute time weighted average

exposure which shall not be exceeded at

any time over a working day.

(b) Computation formulae. The computation formula which shall apply to employee exposure to more than one substance for which 8-hour time weighted averages are listed in subpart Z of 29 CFR Part 1915 in order to determine whether an employee is exposed over the regulatory limit is as follows:

(1)(i) The cumulative exposure for an 8-hour work shift shall be computed as

follows:

$$E = (C_aT_a + C_bT_b + \dots C_nT_n) \div 8$$
Where:

E is the equivalent exposure for the working shift.

C is the concentration during any period of time T where the concentration remains constant.

T is the duration in hours of the exposure at the concentration C.

The value of E shall not exceed the 8-hour time weighted average specified in subpart Z or 29 CFR part 1915 for the material involved.

(ii) To illustrate the formula prescribed in paragraph (d)(1)(i) of this section, assume that Substance A has an 8-hour time weighted average limit of 100 ppm noted in Table Z. Assume that an employee is subject to the following exposure:

Two hours exposure at 150 ppm Two hours exposure at 75 ppm Four hours exposure at 50 ppm

Substituting this information in theformula, we have

 $(2\times150+2\times75+4\times50)$ ÷8=81.25 ppm

Since 81.25 ppm is less than 100 ppm, the 8-hour time weighted average limit, the exposure is acceptable.

(2)(i) In case of a mixture of air contaminants an employer shall compute the equivalent exposure as follows:

$E_m\!=\!(C_1\!\div\! L_1\!+\!C_2\!\div\! L_2)\!+\!$	 $\{C_n + L_n\}$
Where.	

E_m is the equivalent exposure for the mixture. C is the concentration of a particular contaminant.

L is the exposure limit for that substance specified in subpart Z of 29 CFR part 1915.

The value of E_m shall not exceed unity (1).

(ii) To illustrate the formula prescribed in paragraph (d)(2)(i) of this section, consider the following exposures:

tion of 8 hr. exposure (ppm)	8 hr. TWA PEL (ppm)
500 45	1000 200 200
	exposure (ppm)

Substituting in the formula we have: $Em = 500 \pm 1,000 + 45 \pm 200 + 40 \pm 200$ Em = 0.500 + 0.225 + 0.200 Em = 0.925

Since Em is less than unity (1), the exposure combination is within acceptable limits.

(c) Methods of compliance. To achieve compliance with paragraphs (a) and (b) of this section administrative or engineering controls must first be implemented whenever feasible. When such controls are not feasible to achieve full compliance, protective equipment or other protective measures shall be used to keep the exposure of employees to air contaminants within the limits prescribed in this section. Any equipment and technical measures used for this purpose must first be approved for each particular use by a competent industrial hygienist or other technically qualified person.

(d) Effective and start-up dates—(1)
Effective date. The effective date for the

permissible exposure limits specified in the Final Rule Limits columns of Table Z, Shipyards is [90 days after date of publication in the Federal Register].

(2) Start-up dates. (i) The permissible exposure limits specified in the Final Rule Limits columns of Table Z, Shipyards shall be achieved by any reasonable combination of engineering controls, work practices and personal protective equipment from the effective date through [4 years after date of publication in the Federal Register].

(ii) The permissible exposure limits specified in the Final Rule Limits columns of Table Z, Shipyards shall be achieved by the method of compliance specified in paragraph (c) of this section commencing [4 years after date of publication in the Federal Register].

(iii) The skin designation in the Final Rule Limits columns shall be complied with commencing on the effective date.

(3) Transitional provision. The permissible exposure limits specified in the Transitional Limits columns of Table Z, Shipyards (which are a Time Weighted Average unless proceeded by a "C" in which case they are a ceiling) shall be achieved by the methods of compliance specified in paragraph (c) of this section from the effective date through [4 years after date of publication in the Federal Register].

(4) Stays. If any new or amended provisions or new or revised limits for any substance or substances are either administratively stayed or judicially stayed or vacated, then the existing provisions or limits for those substances specified in the Transitional Limits columns of Table Z, Shipyards shall remain in effect until such stay is lifted, or indefinitely if the limit is vacated.

Poolingles:											

Footnotes:

* Same as Final Rule Limits.

* See Mineral Dusts Table.

* Use Asbestos Limit 1910.1001.

* Use Asbestos Limit 1910.1001 for asbestiform; for non-asbestiform see 1910.1101.

* The transitional PELs are 8-hour TWAs unless otherwise noted; a (C) denotes a ceiling limit.

* As determined from breathing-zone air samples.

* Parts of vapor or gas per million parts of contaminated air by volume at 25°C and 760 torr.

* Milligrams of substance per cubic meter of air. When entry is in this column only, the value is exact; when listed with a ppm entry, it is approximate.

* Duration is for 15 minutes, unless otherwise noted.

* The CAS numbers for information only. Enforcement is based on the substance name. For an entry covering more than one metal compound, measured as the metal, the CAS number for the individual compounds.

* Compliance with the subtilising part assessed by sampling with a high volume sampler (600-800 liters per minute) for at least 60 minutes.

* Compliance with the subtilising assessed by sampling with a high volume sampler (600-800 liters per minute) for at least 60 minutes.

* For those substances for which a full standard exists, exposure limits are provided in the binding requirements are as set forth in the single-substance standard.

* For sectors excluded from 1910,1028 the limit is 10 ppm and see 1910,1000. Table Z-2 for ceiling limits.

* Where OSHA has published for a substance separately from this rulemaking but has not issued a final rule, the proposed new limit is published in the Final Rule Limits columns. However, the proposed new limit is presented just for information purposes, and the substances are not being considered in this

The 1970 TLVs use letter designations instead of a numerical value as follows:

A 1 Because of the hip incidence of cancer, either in humans or in animals, no exposure or contact by any route, respiratory, oral or skin should be permitted.

A 2 Bolyteratelucorechylene decomposition products. Because these products, but air concentrations should be minimal.

A 3 Gasoline and/or Petroleum Distillates. The composition of the products, but air concentrations should be minimal and/or Petroleum Distillates. The composition of these materials varies greatly and thus a single TLV for all types of these materials is no longer applicable. The content of benzene, other aromatics and additives should be determined to arrive at the appropriate TLV.

II. OSHA proposes to amend 29 CFR Part 1917 as follows:

PART 1917—MARINE TERMINALS

 It is proposed to revise the authority citation for part 1917 to read as follows:

Authority: Sec. 41, Longshore and Harbor Workers Compensation Act (33 U.S.C. 941); secs. 4, 6, 8, Occupational Safety and Health Act of 1970 (29 U.S.C. 653, 655, 657); Secretary of Labor's Order No. 12–71 (36 FR 8754), 8–76 (41 FR 25059), 9–83 (48 FR 35736) or 1–90 (55 FR 9033), as applicable; 29 CFR Part 1911.

Section 1917.28 also issued under 5 U.S.C.

553.

2. It is proposed to amend \$ 1917.1 by revising paragraph (a)(2)(ii) as follows:

§ 1917.1 Scope and applicability.

(a) * * *

(2) * *

(i) * * *

- (ii) Toxic and hazardous substances.
 29 CFR 1917, Subpart Z applies generally except when a substance or cargo is contained within a sealed intact means of packaging or containment complying with Department of Transportation or International Maritime Organization requirements; 1
- 3. It is proposed to amend § 1917.2 by revising paragraph (p)(1) as follows:

§ 1917.2 Definitions.

(p) Hazardous cargo, material, substance or atmosphere means:

(1) Any substance listed in 29 CFR
1917, subpart Z. A hazardous
atmosphere, or hazardous level of a
hazardous cargo, material, substance or
atmosphere or a hazardous vapor
concentration exists for any substance
covered by 29 CFR 1917 or subpart Z
when the exposure level in the marine
terminal workplace is above the
permissible exposure limits specified in
29 CFR 1917, subpart Z;

4. It is proposed to amend § 1917.23 by revising paragraph (a) to read as follows:

§ 1917.23 Hazardous atmospheres and substances. (See § 1917.2 (p)).

(a) Purpose and scope. This section covers areas in which the employer is aware that a hazardous atmosphere or substance may exist except that 29 CFR 1917, subpart Z always applies pursuant to its terms, and except that paragraphs (b) through (e) of this section do not

apply where one or more of the following sections apply: Section 1917.22 Hazardous cargo; § 1917.24 Carbon monoxide; § 1917.25 Fumigants, pesticides, insecticides and hazardous preservatives; § 1917.73 Menhaden terminals; § 1917.152 Welding, cutting, and heating (hot work); and § 1917.153 Spray painting.

5. It is proposed to amend § 1917.24 by revising paragraph (a) as follows:

§ 1917.24 Carbon monoxide.

(a) Exposure limits. The carbon monoxide content of the atmosphere in a compartment room, building, vehicle, railcar or any enclosed space shall be maintained at not more than 35 ppm (0.0035%) as an 8-hour time weighted average and employees shall be removed from the enclosed space if the carbon monoxide concentration exceeds 100 parts per million (0.01%). The short term exposure limit in outdoors non-enclosed spaces shall be 200 ppm (0.02%) measured over a 5 minute period.

Subparts H-Y [Reserved]

6. It is proposed to reserve Subparts H-Y and to add a new Subpart Z consisting of § 1917.1000 to read as follows:

Subpart Z—Toxic and Hazardous Substances

§ 1917.1000 Air Contaminants.

(a) Exposure limits. An employee's exposure to any substance listed in Table Z, Longshoring and Marine Terminals shall be limited in accordance with the requirements of the following paragraphs of this section:

(1) Final Rule Limits Columns. An employee's exposure to any substance listed in Table Z, Longshoring and Marine Terminals shall not exceed the Time Weighted Average (TWA), Short Term Exposure Limit (STEL) and Ceiling Limit specified for that substance in Table Z, Longshoring and Marine Terminals under the Final Rule Limits columns.

(2) Skin Designation. To prevent or reduce skin absorption, an employee's skin exposure to substances listed in Table Z, Longshoring and Marine Terminals with an "X" in one or both of the Skin Designation columns following the substance name shall be prevented or reduced to the extent necessary in the circumstances through the use of gloves, coveralls, goggles, or other appropriate personal protective equipment, engineering controls or work practices.

(3) Definitions. The following definitions are applicable to Table Z. Longshoring and Marine Terminals:

(i) Time weighted average (TWA) is the employee's average airborne exposure in any 8-hour work shift of a 40-hour work week which shall not be exceeded.

(ii) Short term exposure limit (STEL) is the employee's 15-minute time weighted average exposure which shall not be exceeded at any time during a work day unless another time limit is specified in a parenthetical notation below the limit. If another time period is specified, the time weighted average exposure over that time period shall not be exceeded at any time during the working day.

(iii) Ceiling is the employee's exposure which shall not be exceeded during any part of the work day. If instantaneous monitoring is not feasible, then the ceiling shall be assessed as a 15-minute time weighted average exposure which shall not be exceeded at any time over a working day.

(b) Computation formulae. The computation formula which shall apply to employee exposure to more than one substance for which 8-hour time weighted averages are listed in subpart Z in order to determine whether an employee is exposed over the regulatory limit is as follows:

(1)(i) The cumulative exposure for an 8-hour work shift shall be computed as follows:

 $E\!=\!(C_aT_a\!+\!C_bT_b\!+\,\dots\,C_nT_n)\!+\!8$ Where:

E is the equivalent exposure for the working shift.

C is the concentration during any period of time T where the concentration remains constant.

T is the duration in hours of the exposure at the concentration C.

The value of E shall not exceed the 8hour time weighted average specified in subpart Z or 29 CFR part 1917 for the material involved.

(ii) To illustrate the formula prescribed in paragraph (d)(1)(i) of this section, assume that Substance A has an 8-hour time weighted average limit of 100 ppm noted in Table Z. Assume that an employee is subject to the following exposure:

Two hours exposure at 150 ppm Two hours exposure at 75 ppm Four hours exposure at 50 ppm

Substituting this information in the formula, we have

 $(2\times150+2\times75+4\times50)+8=81.25 \text{ ppm}$

Since 81.25 ppm is less than 100 ppm, the 8-hour time weighted average limit, the exposure is acceptable.

¹ The International Maritime Organization publishes the International Maritime Dangerous Goods Code to aid compliance with the International legal requirements of the International Convention for the Safety of Life at Sea, 1960.

(2)(i) In case of a mixture of air contaminants an employer shall compute the equivalent exposure as follows:

$$\begin{split} E_m \!=\! (C_1 \div L_1 + C_2 \div L_2) + \ \dots \ (C_n \div L_n) \end{split}$$
 Where:

Em is the equivalent exposure for the mixture.

C is the concentration of a particular contaminant.

L is the exposure limit for that substance specified in subpart Z of 29 CFR part 1917.

The value of Em shall not exceed unity

(1).

(ii) To illustrate the formula prescribed in paragraph (d)(2)(i) of this section, consider the following exposures:

Substance	Actual concentra- tion of 8- hour exposure (ppm)	8-hr. TWA PEL (ppm)
В	500	1,000
C	45	200
D	40	200

Substituting in the formula we have:

 $\begin{array}{l} E_m \! = \! 500 \div 1,\!000 + \! 45 \div 200 + \! 40 \div 200 \\ E_m \! = \! 0.500 + \! 0.225 + \! 0.200 \\ E_m \! = \! 0.925 \end{array}$

Since E_m is less than unity (1), the exposure combination is within acceptable limits.

(c) Methods of compliance. To achieve compliance with paragraph (a) of this section administrative or engineering controls must first be implemented whenever feasible. When such controls are not feasible to achieve

full compliance, protective equipment or other protective measures shall be used to keep the exposure of employees to air contaminants within the limits prescribed in this section. Any equipment and technical measures used for this purpose must first be approved for each particular use by a competent industrial hygienist or other technically qualified person. Whenever respirators are used, their use shall comply with § 1917.92 which cross references 29 CFR 1910.134.

(d) Sealed containers. (1) When a substance or cargo is contained within a sealed, intact means of packaging or containment complying with Department of Transportation or International Maritime Organization requirements, then the rest of this section is not applicable.

(2) When sealed, intact means of packaging complying with Department of Transportation or International Maritime Organization requirements containing substances or cargo break, leak or are damaged so that there is a reasonable possibility of leakage, the exposure limits specified in 29 CFR Part 1917, Subpart Z are applicable. These exposure limits shall be met by any reasonable combination of engineering controls work practices and personal protective equipment.

(e) Effective and start-up dates.—(1) effective date. The effective date for the permissible exposure limits specified in the Final Rule Limits columns of Table Z, Longshoring and Marine Terminals is [90 days after date of Publication in the Federal Register].

(2) Start-up dates. (i) The permissible exposure limits specified in the Final

Rule Limits columns of Table Z,
Longshoring and Marine Terminals shall
be achieved by any reasonable
combination of engineering controls,
work practices and personal protective
equipment from the effective date
through [4 years after date of
publication in the Federal Register].

(ii) The permissible exposure limits specified in the Final Rule Limits columns of Table Z, Longshoring and Marine Terminals shall be achieved by the method of compliance specified in paragraph (c) of this section commencing [4 years after date of publication in the Federal Register].

(iii) The skin designation in the Final Rule Limits columns shall be complied with commencing on the effective date.

(3) Transitional provision. The permissible exposure limits specified in the Transitional Limits columns of Table Z, Longshoring and Marine Terminals (which are a Time Weighted Average unless preceded by a "C" in which case they are a Ceiling) shall continue to be achieved by the methods of compliance specified in paragraph (c) of this section from the effective date through [4 years after date of publication in the Federal Register].

(4) If any new or amended provisions or new or revised limits for any substance or substances are either administratively stayed or judicially stayed or vacated, then the existing provisions or limits for those substances specified in the Transitional Limits columns of Table Z, Longshoring and Marine Terminals shall remain in effect until such stay is lifted, or indefinitely if the limit is vacated.

9 Notice and the substance per cubic meter of air. When entry is in this column only, the value is exact when listed with a ppm entry, it is approximate.
9 Notice and the substance per cubic meter of air. When entry is in this column only. The value is exact when listed with the sample (600-800 liters per minutes, unless otherwise noted.
9 The CAS numbers for the individual compounds.
9 The CAS numbers for the individual compounds.
9 The CAS numbers for the individual compounds.
9 The CAS numbers for the individual compounds with the abole for which a full standard exists, exposure limits are provided in the table for information purposes, and the existing limit is 10 ppm TWA and see 1910.1000, Table Z-2 for celling limits.
9 For sectors excluded from 1910.1028 the limit is 10 ppm TWA and see 1910.1000, Table Z-2 for celling limit is presented just for information purposes, and the existing limit is published in the transitional limit column. However, this is presented just for information purposes, and the substances are not being considered in this rulemaking.

not issued a final rule, the proposal is referenced and the existing limit is published in the transitional limit column, and the proposed final limit is just for information purposes, and the substances are not being considered in this rulemaking.

III. OSHA proposes to amend 29 CFR part 1918 as follows:

PART 1918—LONGSHORING

1. It is proposed to amend the authority citation for Part 1918 to read as follows:

Authority: Sec. 41, Longshore and Harbor Workers Compensation Act (33 U.S.C. 941); secs. 4, 6, 8, Occupational Safety and Health Act of 1970 (29 U.S.C. 653, 655, 657); Secretary of Labor's Order No. 12–71 (36 FR 8754), 8–76 (41 FR 25059), 9–83 (48 FR 35736) or 1–90 (55 FR 9033), as applicable.

Sections 1918.90 and 1918.92 also issued under 5 U.S.C. 553 and 29 CFR Part 1911.

2. It is proposed to amend § 1918.93 by revising paragraph (a)(1)(ii), and removing paragraphs (e) and (f) as follows:

§ 1918.93 Ventilation and atmospheric conditions.

- (a) Ventilation requirements with respect to carbon monoxide:
 - (1) (i) * *
- (ii) The carbon monoxide content of the atmosphere in a compartment, room, building, hold, vehicle, railcar or any enclosed space shall be maintained at not more than 35 ppm per million (0.0035%) as an 8-hour time weighted average and employees shall be removed from the enclosed space if the carbon monoxide concentration exceeds 100 parts per million (0.01%). The short term exposure limit in outdoors, non-enclosed spaces shall be 200 ppm (0.02%) measured over a 5 minute period.

Subparts K-Y-[Reserved]

3. It is proposed to reserve subparts K-Y and to add a new subpart Z consisting of § 1918.1000 to read as follows:

Subpart Z—Toxic and Hazardous Substances

§ 1918.1000 Air contaminants.

(a) Exposure limits. An employees exposure to any substance listed in Table Z, Longshoring & Marine Terminals (located at 29 CFR 1917.1000) shall be limited in accordance with the requirements of the following paragraphs of this section:

(1) Final Rule Limits Columns. An employee's exposure to any substance listed in Table Z, Longshoring & Marine Terminals shall not exceed the Time Weighted Average (TWA), Short Term Exposure Limit (STEL) and Ceiling Limit specified for that substance in Table Z—Longshoring and Marine Terminals under the Final Rule Limits columns.

(2) Skin Designation. To prevent or reduce skin absorption, an employee's skin exposure to substances listed in Table Z, Marine Terminals & Longshoring with an "X" in one or both of the Skin Designation columns following the substances name shall be prevented or reduced to the extent necessary in the circumstances through the use of gloves, coveralls, goggles, or other appropriate personal protective equipment, engineering controls or work practices.

(3) Definitions. The following definitions are applicable to Table Z, Longshoring & Marine Terminals:

(i) Time weighted average (TWA) is the employee's average airborne exposure in any 8-hour work shift of a 40-hour work week which shall not be exceeded.

(ii) Short term exposure limit (STEL) is the employee's 15-minute time weighted average exposure which shall not be exceeded at any time during a work day unless another time limit is specified in a parenthetical notation below the limit. If another time period is specified, the time weighted average exposure over that time period shall not be exceeded at any time during the working day.

(iii) Ceiling is the employee's exposure which shall not be exceeded during any part of the work day. If instantaneous monitoring is not feasible, then the ceiling shall be assessed as a 15-minute time weighted average exposure which shall not be exceeded at my time over a working day.

(b) Computation formulae. The computation formula which shall apply to employee exposure to more than one substance for which 8-hour time weighted averages are listed in subpart Z of 29 CFR Part 1918 in order to determine whether an employee is exposed over the regulatory limit is as follows:

(1)(i) The cumulative exposure for an 8-hour work shift shall be computed as follows:

 $E = (C_aT_a + C_bT_b + \dots C_nT_n) \div 8$ Where.

E is the equivalent exposure for the working shift.

C is the concentration during any period of time T where the concentration remains constant.

T is the duration in hours of the exposure at the concentration C.

The value of E shall not exceed the 8hour time weighted average specified in Subpart Z or 29 CFR Part 1918 for the material involved.

(ii) To illustrate the formula prescribed in paragraph (d)(1)(i) of this section, assume that Substance A has an 8-hour time weighted average limit of 100 ppm noted in Table Z. Assume that an employee is subject to the following exposure:

Two hours exposure at 150 ppm Two hours exposure at 75 ppm Four hours exposure at 50 ppm

Substituting this information in the formula, we have

 $(2\times150+2\times75+4\times50)$ ÷8=81.25 ppm

Since 81.25 ppm is less than 100 ppm, the 8-hour time weighted average limit, the exposure is acceptable.

(2)(i) in case of a mixture of air contaminants an employer shall compute the equivalent exposure as follows:

 $E_m {=} (C_1 {\div} L_1 {+} C_2 {\div} L_2) {+} \ \dots \ (C_n {\div} L_n)$ Where:

E_m is the equivalent exposure for the mixture.

C is the concentration of a particular contaminant.

L is the exposure limit for that substance specified in Subpart Z of 29 CFR Part 1918.

The value of E_m shall not exceed unity (1).

(ii) To illustrate the formula prescribed in paragraph (d)(2)(i) of this section, consider the following exposures:

Substance	Actual concentra- tion of 8 hour exposure (ppm)	8 hr. TWA PEL (ppm)
B	500 45 40	1,000 200 200

Substituting in the formula we have:

 $Em = 500 \div 1,000 + 45 \div 200 + 40 \div 200$ Em = 0.500 + 0.225 + 0.200Em = 0.925

Since Em is less than unity (1), the exposure combination is within acceptable limits.

(c) Methods of compliance. To achieve compliance with paragraph (a) of this section administrative or engineering controls must first be implemented whenever feasible. When such controls are not feasible to achieve full compliance, protective equipment or other protective measures shall be used to keep the exposure of employees to air contaminants within the limits prescribed in this section. Any equipment and technical measures used for this purpose must first be approved for each particular use by a competent industrial hygienist or other technically qualified person.

(d) Sealed containers. (1) When a substance or cargo is contained within a sealed, intact means of packaging or containment complying with Department of Transportation or International Maritime Organization requirements then the rest of this section

is not applicable.

(2) When sealed, intact means of packaging complying with Department of Transportation or International Maritime Organization requirements containing substances or cargo break, leak or are damaged so that there is a reasonable possibility of leakage, the exposure limits specified 29 CFR Part 1918, Subpart Z are applicable. These exposure limits shall be met by my reasonable combination of engineering controls, work practices and personal protective equipment.

(e) Effective and start-up dates. (1)
Effective date. The effective date for the
permissible exposure limits specified in
the Final Rule Limits columns of Table
Z, Longshoring & Marine Terminals is
[90 days after date of publication in the

Federal Register].

(2) Start-up dates. (i) The permissible exposure limits specified in the Final Rule Limits columns of Table Z, Longshoring & Marine Terminals shall be achieved by any reasonable combination of engineering controls, work practices and personal protective equipment from the effective date through [4 years after date of publication in the Federal Register].

(ii) The permissible exposure limits specified in the Final Rule Limits columns of Table Z, Longshoring & Marine Terminals shall be achieved by the methods of compliance specified in paragraph (c) of this section commencing [4 years after date of publication in the Federal Register].

(iii) The skin designation in the Final Rule Limits columns shall be complied with commencing on the effective date.

(3) Transitional provision. The permissible exposure limits specified in the Transitional Limits columns of Table Z. Longshoring & Marine Terminals (which are Time Weighted Averages unless proceeded by a "C" in which case they are ceilings) shall continue to be achieved by the methods of compliance specified in paragraph (c) of this section through [4 years after date of publication in the Federal Register].

(4) If any new or amended provisions or new or revised limits for any substance or substances are either administratively stayed or judicially stayed or vacated, then the existing provisions or limits for those substances specified in the Transitional Limits columns of Table Z, Longshoring & Marine Terminals shall remain in effect

until such stay is lifted, or indefinitely if the limit is vacated.

IV. OSHA proposes to amend 29 CFR part 1926 as follows:

PART 1926—CONSTRUCTION

1. It is proposed to revise the authority citation for 29 CFR part 1926, subpart D as follows:

Authority: Sec. 107, Contract Work Hours and Safety Standards Act (Construction Safety Act) (40 U.S.C. 333); secs. 4, 6, 8, Occupational Safety and Health Act of 1970 (29 U.S.C. 653, 655, 657); Secretary of Labor's Order No. 12–71 (36 FR 8754), 8–76 (41 FR 25059), 9–83 (48 FR 35736) or 1–90 (55 FR 9033) as applicable.

Sections 1926.55 and 1926.59 also issued under 5 U.S.C. 553 and 29 CFR Part 1911.

2. It is proposed to revise § 1926.55 to read as follows:

§ 1926.55 Air contaminants.

- (a) Exposure limits. Employers shall prevent exposure of employees to inhalation of substances above the exposure limits specified in Table Z, Construction and minimize skin absorption as follows:
- (1) An employee's exposure to any substance in Table Z, Construction under the Transitional Limits columns, the exposure limit of which is preceded by a "C" shall at no time exceed the exposure limit given for that substance in Table Z, Construction under the Transitional Limits columns.
- (2) An employee's exposure to any substance in Table Z, Construction under the Transitional Limits columns, the exposure limit of which is not preceded by a "C", shall not exceed the 8-hour time Weighted Average given for that substance in Table Z, Construction under the Transitional Limits columns in any 8-hour work shift of a 40-hour work week.
- (3) An employee's exposure to any substance listed in Table Z, Construction shall not exceed the Time Weighted Average (TWA), Short Term Exposure Limit (STEL) and Ceiling Limit specified for that substance in Table Z, Construction under the Final Rule Limits columns.
- (4) To prevent or reduce skin absorption, an employee's skin exposure to substances listed in Table Z, Construction with an "X" in one or both of the Skin Designation columns following the substance name shall be prevented or reduced to the extent necessary in the circumstances through the use of gloves, coveralls, goggles, or other appropriate personal protective equipment, engineering controls or work practices.

(5) The following definitions are applicable to the Final Rule Limits columns of Table Z. Construction:

(i) Time weighted average (TWA) is the employee's average airborne exposure in any 8-hour work shift of a 40-hour work week which shall not be exceeded.

(ii) Short term exposure limit (STEL) is the employee's 15-minute time weighted average exposure which shall not be exceeded at any time during a work day unless another time limit is specified in a parenthetical notation below the limit. If another time period is specified, the time weighted average exposure over that time period shall not be exceeded at any time during the working day.

(iii) Ceiling is the employee's exposure which shall not be exceeded during any part of the work day. If instantaneous monitoring is not feasible, then the ceiling shall be assessed as a 15-minute time weighted average exposure which shall not be exceeded at any time over a working day.

(b) Methods of compliance. To achieve compliance with paragraph (a) of this section, administrative or engineering controls must first be implemented whenever feasible. When such controls are not feasible to achieve full compliance, protective equipment or other protective measures shall be used to keep the exposure of employees to air contaminants within the limits prescribed in this section. Any equipment and technical measures used for this purpose must first be approved for each particular use by a competent industrial hygienist or other technically qualified person. Whenever respirators are used, their use shall comply with § 1926.103.

(c) Computation formulae. The computation formula which shall apply to employee exposure to more than one substance for which 8-hour time weighted averages are listed in Table Z. Construction in order to determine whether an employee is exposed over the regulatory limit is as follows:

(1)(i) The cumulative exposure for an 8-hour work shift shall be computed as follows:

 $E = (C_a T_a + C_b T_b + . . . C_n T_n) \div 8$ Where:

E is the equivalent exposure for the working shift.

C is the concentration during any period of 'time T where the concentration remains constant.

T is the duration in hours of the exposure at the concentration C.

The value of E shall not exceed the 8-hour time weighted average specified in Table Z. Construction for the material involved.

(ii) To illustrate the formula prescribed in paragraph (d)(1)(i) of this section, assume that Substance A has an 8-hour time weighted average limit of 100 ppm noted in Table Z. Assume that an employee is subject to the following exposure:

Two hours exposure at 150 ppm Two hours exposure at 75 ppm Four hours exposure at 50 ppm

Substituting this information in the formula, we have:

 $(2\times150+2\times75+4\times50)$ ÷ 8=81.25 ppm

Since 81.25 ppm is less than 100 ppm, the 8-hour time weighted average limit, the exposure is acceptable.

(2)(i) In case of a mixture of air contaminants an employer shall compute the equivalent exposure as follows:

 $E_m = (C_1 \div L_1 + C_2 \div L_2) + \dots (C_n \div L_n)$ Where:

E_m is the equivalent exposure for the mixture.

C is the concentration of a particular
contaminant.

L is the exposure limit for that substance specified in Table Z, Construction.

The value of Em shall not exceed unity (1).

(ii) To illustrate the formula prescribed in paragraph (d)(2)(i) of this section, consider the following exposures:

Substance	Actual concentra- tion of 8 hour exposure (ppm)	8 hr. TWA PEL (ppm)
B	500 45 40	1000 200 200

Substituting in the formula we have:

 $\begin{array}{l} Em = 500 \div 1,000 + 45 \div 200 + 40 \div 200 \\ Em = 0.500 + 0.225 + 0.200 \\ Em = 0.925 \end{array}$

Since Em is less than unity (1), the exposure combination is within

acceptable limits.

(d) Effective and start-up dates—(1) Effective date. The effective date for the permissible exposure limits specified in the Final Rule Limits columns of Table Z, Construction is [90 days after date of publication in the Federal Register].

(2) Start-up dates. (i) The permissible exposure limits specified in the Final Rule Limits columns of Table Z, Construction shall be achieved by any reasonable combination of engineering controls, work practices and personal protective equipment from the effective

date through [4 years after date of publication in the Federal Register].

(ii) The permissible exposure limits specified in the Final Rule Limits columns of Table Z, Construction shall be achieved by the method of compliance specified in paragraph (b) of this section commencing [4 years after date of publication in the Federal Register].

(iii) The skin designations in the Final Rule Limits columns shall be complied with commencing on the effective date.

(3) Transitional provision. The permissible exposure limits specified in the Transitional Limits columns of Table Z, Construction shall continue to be achieved by the methods of compliance specified in paragraph (b) of this section through [4 years after the date of publication in the Federal Register].

(4) If any new or amended provisions or new or revised limits for any substance or substances are either administratively stayed or judicially stayed or vacated, then the existing provisions or limits for those substances specified in the Transitional Limits columns of Table Z, Construction shall remain in effect until such stay is lifted, or indefinitely if the limit is vacated.

V. OSHA proposes to amend 29 CFR part 1928 as follows:

PART 1928—AGRICULTURE

 It is proposed to revise the authority citation for part 1928 to read as follows:

Authority: Secs. 6, 8 Occupational Safety and Health Act, 29 U.S.C. 655, 657; Secretary of Labor's Order, No. 12–7 (36 FR 8754), 8–76 (41 FR 25059), 9–83 (48 FR 35736) or 1–90 (55 FR 9033) as applicable; and 29 CFR Part 1911.

Subparts J-Y-[Reserved]

2. It is proposed to reserve Subparts J-Y and to add a new Subpart Z consisting of § 1928.1000 to read as follows:

Subpart Z—Toxic and Hazardous Substances

§ 1928.1000 Air contaminants.

(a) Exposure limits. An employee's exposure to any substance listed in Table Z, Agriculture shall be limited in accordance with the requirements of the following paragraphs of this section:

(1) Final Rule Limit Columns. An employee's exposure to any substance listed in Table Z, Agriculture shall not exceed the Time Weighted Average (TWA), Short Term Exposure Limit (STEL) and Ceiling Limit specified for that substance in Table Z, Agriculture under the Final Rule Limits columns.

(2) Skin Designation. To prevent or reduce skin absorption, an employee's skin exposure to substances listed in Table Z, Agriculture with an "X" in the Skin Designation column following the substance name shall be prevented or reduced to the extent necessary in the circumstances through the use of gloves, coveralls, goggles, or other appropriate personal protective equipment, engineering controls or work practices.

(3) Definitions. The following definitions are applicable to the Final Rule Limits columns of Table Z,

Agriculture:

(i) Time weighted average (TWA) is the employee's average airborne exposure in any 8-hour work shift of a 40-hour work week which shall not be exceeded.

fii) Short term exposure limit (STEL) is the employee's 15-minute time weighted average exposure which shall not be exceeded at any time during a work day unless another time limit is specified in a parenthetical notation below the limit. If another time period is specified, the time weighted average exposure over that time period shall not

be exceeded at any time during the working day.

(iii) Ceiling is the employee's exposure which shall not be exceeded during any part of the work day. If instantaneous monitoring is not feasible, then the ceiling shall be assessed as a 15-minute time weighted average exposure which shall not be exceeded at any time over a working day.

(b) Computation formulae. The computation formula which shall apply to employee exposure to more than one substance for which 8-hour time weighted averages are listed in subpart Z of 29 CFR Part 1918 in order to determine whether an employee is exposed over the regulatory limit is as follows:

(1)(i) The cumulative exposure for an 8-hour work shift shall be computed as follows:

$$\begin{split} E \!=\! \left(C_a T_a \!+\! C_b T_b \!+\! , \quad .C_n T_n \right) \!+\! 8 \\ Where: \end{split}$$

E is the equivalent exposure for the working shift.

C is the concentration during any period of time T where the concentration remains constant.

T is the duration in hours of the exposure at the concentration C.

The value of E shall not exceed the 8-hour time weighted average specified in Subpart Z or 29 CFR Part 1918 for the material involved.

(ii) To illustrate the formula prescribed in paragraph (d)(1)(i) of this section, assume that Substance A has an 8-hour time weighted average limit of 100 ppm noted in Table Z. Assume that an employee is subject to the following exposure:

Two hours exposure at 150 ppm Two hours exposure at 75 ppm Four hours exposure at 50 ppm

Substituting this information in the formula, we have:

 $(2\times150+2\times75+4\times50)+8=81.25$ ppm

Since 81.25 ppm is less than 100 ppm, the 8-hour time weighted average limit, the exposure is acceptable.

(2)(i) in case of a mixture of air contaminants an employer shall compute the equivalent exposure as follows:

 $Em = (C_1 + L_1 + C_2 + L_4) + \dots (C_n + L_n)$ Where:

 E_m is the equivalent exposure for the mixture. C is the concentration of a particular contaminant.

L is the exposure limit for that substance specified in subpart Z of 29 CFR part 1918. The value of Em shall not exceed unity (1).

(ii) To illustrate the formula prescribed in paragraph (d)(2)(i) of this section, consider the following exposures:

Substance	Actual concentra- tion of 8 hour exposure (ppm)	8 hr. TWA PEL (ppm)
B	500 45 40	1000 200 200

Substituting in the formula we have:

$$\begin{split} E_m &= 500 \div 1,000 + 45 \div 200 + 40 \div 200 \\ E_m &= 0.500 + 0.225 + 0.200 \end{split}$$

 $E_m = 0.925$

Since Em is less than unity (1), the exposure combination is within acceptable limits.

(c) Methods of compliance. To achieve compliance with paragraph (a) of this section administrative, work practice or engineering controls must first be implemented whenever feasible. When such controls are not feasible, respirators or other protective measures shall be used to keep the exposure of employees to air contaminants within the limits prescribed in this section. Whenever respirators are used, their use shall comply with 29 CFR § 1910.134.

(d) Effective and Start-up dates—(1) Effective date. The effective date for the permissible exposure limits specified in the Final Rule Limits columns of Table Z, Agriculture is [90 days after date of publication in the Federal Register].

(2) Start-up dates (i) The permissible exposure limits specified in the Final Rule Limits columns of Table Z, Agriculture shall be achieved by any reasonable combination of engineering controls, administrative controls, work practices and personal protective equipment effective [1 year after date of publication in the Federal Register].

(ii) The permissible exposure limits specified in the Final Rule Limits columns of Table Z. Agriculture shall be achieved by the method of compliance specified in paragraph (b) of this section effective [4 years after date of publication in the Federal Register].

(iii) The skin designations in the Final Rule Limits columns shall be complied with commencing [1 year after date of publication in the Federal Register].

Footnotes:

** As determined by breathing-zone air samples.

*Parts of vapor or gas per million parts of contaminated air by volume at 25°C and 760 torr.

*Milligrams of substance per cubic meter of air. When entry is in this column only, the value is exact, when listed with a ppm entry, it is approximate.

*Duration is for 15 minutes, unless otherwise noted.

*The CAS number is for information only. Enforcement is based on the substance name. For an entry covering more than one metal compound, measured as the metal, the CAS number for the metal is given—not CAS numbers for the individual compounds.

*Compliance with the subtilisins PEL is assessed by sampling with a high volume sampler (600–800 liters per minute) for at least 60 minutes.

*The reference to the comprehensive standard is for informational purposes and is not binding in agriculture. Only the exposure limits and 1928.1000 are binding in agriculture.

binding in agriculture.

* For sectors excluded from 1910.1028, the limit is 10 ppm and see 1910.1000, Table Z-2 for ceiling limits.

* Where OSHA has published a proposal for a substance separate from this rulemaking but has not issued a final rule. The proposal is referenced, and the proposed final limit is placed in the table. However, this is presented just for information purposes, and the substances are not being considered in this rulemaking.

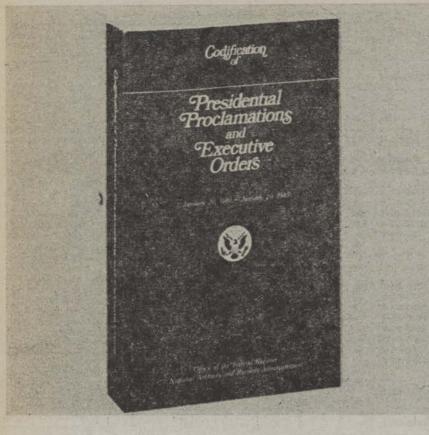

XI. Appendices

For "Sampling and Analytical Methods" see 54 FR 2961-2983, January 19, 1989. Additional and updated material on this issue will be found in the docket established for this rulemaking (H-020-A).

DO LO DEST ENLISED.

For those of you who must keep informed about Presidential Proclamations and Executive Orders, there is a convenient reference source that will make researching these documents much easier.

Arranged by subject matter, this edition of the Codification contains proclamations and Executive orders that were issued or amended during the period April 13, 1945, through January 20, 1989, and which have a continuing effect on the public. For those documents that have been affected by other proclamations or Executive orders, the codified text presents the amended version. Therefore, a reader can use the Codification to determine the latest text of a document without having to "reconstruct" it through extensive research.

Special features include a comprehensive index and a table listing each proclamation and Executive order issued during the 1945–1989 period—along with any amendments—an indication of its current status, and, where applicable, its location in this volume.

Guide to Record Retention Requirements

in the Code of Federal Regulations (CFR)

GUIDE: Revised January 1, 1992

The GUIDE to record retention is a useful reference tool, compiled from agency regulations, designed to assist anyone with Federal recordkeeping obligations.

The various abstracts in the GUIDE tell the user (1) what records must be kept, (2) who must keep them, and (3) how long they must be kept.

The GUIDE is formatted and numbered to parallel the CODE OF FEDERAL REGULATIONS (CFR) for uniformity of citation and easy reference to the source document.

Compiled by the Office of the Federal Register, National Archives and Records Administration

Public Laws

102d Congress, 1st Session, 1991

Pamphlet prints of public laws, often referred to as slip laws, are the initial publication of Federal laws upon enactment and are printed as soon as possible after approval by the President. Legislative history references appear on each law. Subscription service includes all public laws, issued irregularly upon enactment, for the 102d Congress, 1st Session, 1991.

(Individual laws also may be purchased from the Superintendent of Documents, Washington, DC 20402-9328. Prices vary. See Reader Aids Section of the Federal Register for announcements of newly enacted laws and prices).

The Federal Register

Regulations appear as agency documents which are published daily in the Federal Regulations

The Federal Register, published daily, is the official publication for notifying the public of proposed and final regulations. It is the tool for you to use to participate in the rulemaking process by commenting on the proposed regulations. And it keeps you up to date on the Federal regulations currently in effect.

Mailed monthly as part of a Federal Register subscription are: the LSA (List of CFR Sections Affected) which leads users of the Code of Federal Regulations to amendatory actions published in the daily Federal Register; and the cumulative Federal Register Index.

The Code of Federal Regulations (CFR) comprising approximately 196 volumes contains the annual codification of the final regulations printed in the Federal Register. Each of the 50 titles is updated annually.

Individual copies are separately priced. A price list of current CFR volumes appears both in the Federal Register each Monday and the monthly LSA (List of CFR Sections Affected). Price inquiries may be made to the Superintendent of Documents, or the Office of the Federal Register.
